

Example The quotient space of a prop. disc. action is not always Hausdorff
 Fix $a > 1$, let \mathbb{Z} act on $X = \mathbb{R}^2 \setminus \{0\}$ by $f^n(x, y) = (a^n x, a^{-n} y)$, $n \in \mathbb{Z}$.
 The open quadrants and open half-axes are invariant sets. Each open quadrant is foliated by arcs of hyperbola, also invariant

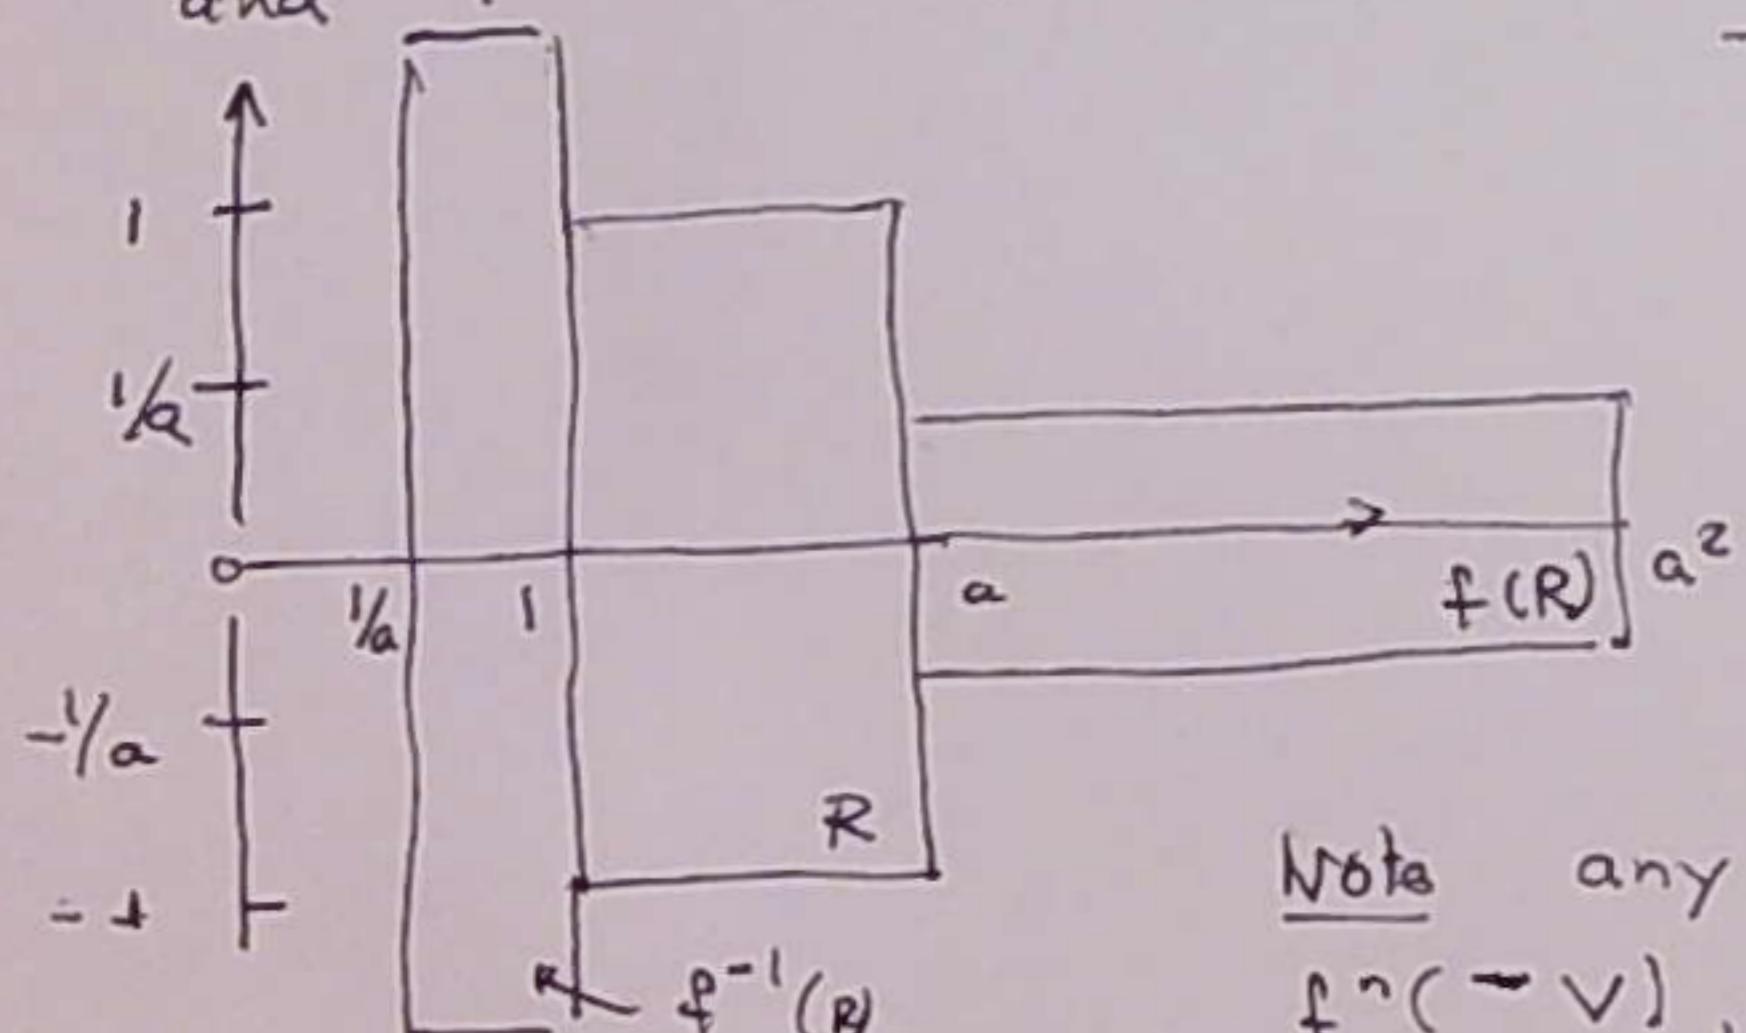

the open interval $(1, a)$ on the $\{x > 0\}$ half-axis intersects each orbit

exactly once. So X/\mathbb{Z} contains a homeomorphic copy of $S^1 = \mathbb{R}_+/\mathbb{Z}$, correct

We get a total of 4 circles in X/\mathbb{Z} , one for each half-axis.

Thus as a set, X/\mathbb{Z} is the disjoint union of 4 cylinders C_1, \dots, C_4 and 4 circles S_1, \dots, S_4 .

The open rectangle $(1, a) \times (-1, 1) = \overset{\circ}{R}$ is mapped disjointly from itself. Thus $p = \pi(t, 0) \in S_1$ ($t \in (1, a)$) has a homeomorphic copy of $\overset{\circ}{R}$ as a nbd in X/\mathbb{Z} (this shows X/\mathbb{Z} is locally euclidean).

Note any nbd of a point in R intersects some $f^n(-V)$, where V is any compact nbd of a pt. in Σ . Thus points in $\overset{\circ}{S}_1$ cannot be separated (by nbds in X/\mathbb{Z}) from points in the cylinder C_1 (or from points in C_4).

(2)

In the same way, any nbd of a pt in Σ_1 intersects $f^n(A)$ for some n , where A is any nbd of a pt in $(1, a) \subset \{x > 0\}$: points in C_1 cannot be separated (by nbds in X/Z) from points in the circle S_1 (or from pts in the circle S_2). The quotient topology in X/Z is locally euclidean, but not Hausdorff.

Exercise (i) Let $\Gamma = \{(x, gx); g \in G, x \in X\}$ be the graph of the action. Then if Γ is closed in $X \times X$, the quotient space X/G is Hausdorff. (Here $G \hookrightarrow X$ prop.-disc., X Hausdorff.)

(ii) Suppose (X, d) is metric, and G acts by isometries: $d(gx, gy) = d(x, y) \quad \forall g, x, y$. Then Γ is closed.

Exercise Let X be a diff'ble manifold (C^r atlas, $r \geq 1$) and G act on X by C^r diffeomorphisms, properly discontinuously and with closed graph. Then

- (i) X/G is locally euclidean, Hausdorff, 2nd ctble. (^{topological} mfd.)
- (ii) X/G admits a C^r atlas.
