Hairy Graphs and the Unstable Homology 
Of $\text{Mod}(g,s)$, $\text{Out}(F_n)$ and $\text{Aut}(F_n)$ 

Jim Conant, Martin Kassabov, and Karen Vogtmann

Abstract. For every cyclic operad $\mathcal{O}$ there is an associated Lie algebra $\mathfrak{h}^\mathcal{O}$ of symplectic derivations of positive degree. For the associative and Lie operads, Kontsevich used his graph homology theory to prove that the Lie algebra homology of $\mathfrak{h}^\mathcal{O}$ computes the cohomology of mapping class groups of punctured surfaces and outer automorphism groups of free groups, respectively. In this paper we introduce a hairy graph homology theory for $\mathcal{O}$ and show that the homology of $\mathfrak{h}^\mathcal{O}$ embeds in hairy graph homology via a trace map which generalizes the trace map defined by S. Morita. We show that the image of this trace is large, which allows us to determine the exact abelianization of $\mathfrak{h}^\mathcal{O}$ for the associative operad. For the Lie operad we find new pieces of the abelianization related to classical modular forms for $\text{SL}(2,\mathbb{Z})$. Using these new pieces, we construct new cycles for the unstable homology of $\text{Out}(F_n)$ and $\text{Aut}(F_n)$.

This paper is the first of two. In the second paper we use representation theory to determine the image of the trace map precisely and show how the theory we develop is related to Loday’s dihedral homology and to Getzler and Kapranov’s theory of modular operads.

Introduction

In two seminal papers [17, 16], Kontsevich showed that the homology of certain Lie algebras of symplectic derivations computes the cohomology of the mapping class groups $\text{Mod}(g,s)$ of punctured surfaces and of the outer automorphism groups $\text{Out}(F_n)$ of free groups. The proof proceeds by identifying the chain complexes for both the Lie algebra homology and the group cohomology with chain complexes generated by graphs with extra structure. For mapping class groups this extra structure is based on the structure of the associative operad $\mathcal{Assoc}$, and for $\text{Out}(F_n)$ it is based on the Lie operad $\mathcal{Lie}$. In [4] Conant and Vogtmann generalized Kontsevich’s construction to define a Lie algebra $\mathfrak{h}^\mathcal{O}$ of symplectic derivations and an associated $\mathcal{O}$-graph homology for any cyclic operad $\mathcal{O}$ of finite-dimensional vector spaces. They then used their interpretation of Kontsevich’s work to produce extra algebraic structure on the chain complexes which compute the homology of mapping class groups and $\text{Out}(F_n)$.

The Lie algebra interpretation of the homology of $\text{Mod}(g,s)$ and $\text{Out}(F_n)$ was put to good use by Morita, who used the trace maps he had earlier defined from the Lie algebras $\mathfrak{h}^\mathcal{Lie}$ and $\mathfrak{h}^{\mathcal{Assoc}}$ to abelian Lie algebras to pull back cohomology classes to $H^*(\mathfrak{h}^\mathcal{O})$, and thus via a dual version of Kontsevich’s theorem to homology classes in $\text{Mod}(g,s)$ and $\text{Out}(F_n)$. Several of these classes have been shown to be non-trivial in homology ([2, 4, 20, 12]), and
they are all conjectured to be non-trivial. We remark that the stable homology of both \( \text{Mod}(g \hookrightarrow s) \) and \( \text{Out}(F_n) \) is well understood (see \([8, 19]\)) but the unstable homology remains quite mysterious, and all of Morita’s classes lie in the unstable range.

In the current paper we define a “hairy” version of \( \mathcal{O} \)-graph homology. The chain complex \( C_* \mathcal{H}^\mathcal{O} \) for hairy \( \mathcal{O} \)-graph homology is a hybrid of the chain complex for \( \mathfrak{h}^\mathcal{O} \) and that for ordinary (unhairy) \( \mathcal{O} \)-graph homology; in the hairy version \( \mathcal{O} \)-graphs are allowed to have univalent vertices, which are labeled by elements of a symplectic vector space. The central construction of this paper is a chain map

\[
\text{Tr}: C_k(\mathfrak{h}^\mathcal{O}) \to C_k \mathcal{H}^\mathcal{O}
\]

which is a generalization of Morita’s trace map. In Theorem 3.3, we show that \( \text{Tr} \) is an injection on homology. In particular, in dimension 1 this gives an embedding of the abelianization of \( \mathfrak{h}^\mathcal{O} \) into \( H_1(\mathcal{H}^\mathcal{O}) \).

We next show that the image of the trace map surjects onto a large subspace of hairy \( \mathcal{O} \)-graph homology (see Theorem 3.6), so that hairy \( \mathcal{O} \)-graph homology provides both upper and lower “bounds” on the homology of \( \mathfrak{h}^\mathcal{O} \). We use these bounds to calculate the abelianization of \( \mathfrak{h}^\mathcal{O} \) in the case \( \mathcal{O} = \text{Assoc} \) (Theorem 6.5). We find that the abelianization is precisely equal to the piece determined by Morita in \([21]\). We recently learned that Morita, Sakasai and Suzuki have independently obtained this result using different methods \([22]\).

Morita also found pieces of the abelianization in the case \( \mathcal{O} = \text{Lie} \), and conjectured that these formed the entire abelianization \([20]\,\text{Conjecture 6.1}\). In Propositions 7.4 and 7.5 we recover his results, but also find that the abelianization is much larger than expected. In particular, it supports a grading corresponding to the rank of the fundamental groups of hairy graphs, and Morita’s pieces correspond to ranks zero and one. In Theorem 7.8 we give a general description of the rank \( r \) piece in terms of the cohomology of \( \text{Out}(F_r) \) with twisted coefficients. This allows us in particular to identify the rank two piece with spaces of modular forms via the Eichler-Shimura isomorphism (Theorem 7.10). Preliminary calculations indicate that the rank 3 piece is also highly nontrivial and the dimensions appear related to modular forms, but we will defer these calculations to another paper.

Using the new rank two pieces of the abelianization for \( \mathcal{O} = \text{Lie} \) we construct an embedding

\[
S^2(M_{2k}^0)^* \hookrightarrow Z_{4k-2}(\text{Out}(F_{2k+1}; \mathbb{Q})
\]

into cycles for \( \text{Out}(F_{2k+1}) \), where \( M_{2k}^0 \) is the vector space of cusp forms for \( \text{SL}(2, \mathbb{Z}) \) of weight \( 2k \) (Theorem 8.4). At this point, we do not know if the image is non-trivial in homology. On the other hand, using a theorem of Gray that relates the homology of \( \text{Aut}(F_n) \) to a certain twisted homology of \( \mathfrak{h}^\text{Lie} \), in Theorem 8.7 we produce a series of cycles \( e_{4k+3} \in Z_{4k+3}(\text{Aut}(F_{2k+3}); \mathbb{Q}) \) which at least in low dimensions are related to Eisenstein series. With the help of a computer it can be shown that \( e_7 \) and \( e_{11} \) represent nontrivial homology classes. The class in \( e_7 \in H_7(\text{Aut}(F_5)) \) coincides with a class found many years earlier by a computer calculation by F. Gerlits \([10]\). This class had not previously seemed to fit into the picture of classes coming from the abelianization of \( \mathfrak{h}^\text{Lie} \).

In the final section of this paper we note that hairy Lie graph homology is related to the cohomology of mapping class groups of certain punctured 3-manifolds, as defined in \([15]\).
Specifically, let $M_{n,s}$ be the compact 3-manifold obtained from the connected sum of $n$ copies of $S^1 \times S^2$ by deleting the interiors of $s$ disjoint balls, and let $\Gamma_{n,s}$ be the quotient of the mapping class group of $M_{n,s}$ by the normal subgroup generated by Dehn twists along embedded 2-spheres. Then hairy graph homology computes the cohomology of $\Gamma_{n,s}$ with certain twisted coefficients (Theorem 9.1).

This paper is the first in a series of two papers. In this paper we have concentrated on the theory needed to understand the abelianization of $\mathcal{H}$ and applications to the homology of mapping class groups and automorphism groups of free groups. In the sequel we will use representation theory to obtain a precise description of the image of the trace map as the kernel of an operator on hairy $\mathcal{O}$-graph homology. We will also show how to use higher hairy graph homology to produce classes in the cohomology of $\mathcal{H}$, yielding more potential unstable homology classes for $\text{Aut}(F_n)$, $\text{Out}(F_n)$, and $\text{Mod}(g,s)$. Finally, we will explain connections between hairy graph homology and Getzler and Kapranov’s theory of modular operads, and also with Loday’s dihedral homology.

1. Review of the Lie algebra associated to a cyclic operad and its (co)homology

All vector spaces in this paper will be over a fixed field $k$ of characteristic 0 and have either finite or countable dimension. In this section, we also fix a cyclic operad $\mathcal{O}$ in the category of $k$-vector spaces. Let $\mathcal{O}(\langle m \rangle)$ denote the vector space spanned by operad elements with $m$ input/output slots (any one of which can serve as the output for the other $(m-1)$ inputs). We will assume that the vector spaces $\mathcal{O}(\langle m \rangle)$ are finite-dimensional for each $m$, and we fix a basis for each $\mathcal{O}(\langle m \rangle)$.

1.1. The Lie algebra $\mathcal{L} = \mathcal{L}\mathcal{O}_V$. We recall from [4] how to construct a Lie algebra from $\mathcal{O}$ and a symplectic vector space $(V, \omega)$. Our main example will be the $2n$-dimensional vector space $V_n$ with the standard symplectic form. It will be convenient to specify a symplectic basis $B_n = \{p_1, \ldots, p_n, q_1, \ldots, q_n\}$ for $V_n$, so the matrix of $\omega$ in the basis $B_n$ is

$$
\begin{pmatrix}
0 & I \\
-I & 0
\end{pmatrix}
$$

We will also often consider the direct limit $V_\infty$ of the $V_n$ with respect to the natural inclusion, with basis $B_\infty$. For $x \in B_\infty$ the dual $x^*$ is given by $p_i^* = q_i$ and $q_i^* = -p_i$.

Definition 1.1. An $\mathcal{O}$-spider is an operad element whose input/output slots $\lambda$ (called legs) are each decorated with an element $x_\lambda \in V$. For $V = V_n$, if the operad element is a basis element of $\mathcal{O}$ and the labels are in $B_n$, the spider is called a basic $\mathcal{O}$-spider.

The Lie algebra $\mathcal{L} \mathcal{O}_V$ is generated (as a vector space) by $\mathcal{O}$-spiders. If $V = V_n$ the basic spiders are a basis for $\mathcal{L} \mathcal{O}_V$. We will often abbreviate $\mathcal{L} \mathcal{O}_V$ to $\mathcal{L} \mathcal{O}_n$. 
Two spiders $s_1$ and $s_2$ can be fused into a single spider by using a leg $\lambda_1$ from the first as output and a leg $\lambda_2$ of the second as input and performing operad composition. The unused legs retain their labels, and the resulting $O$-spider is multiplied by the symplectic pairing $\omega(x_{\lambda_1}, x_{\lambda_2})$ of the labels. We denote the end result of this by $(s_1 \cdot s_2)(\lambda_1, \lambda_2)$.

Note that if each $s_i$ is a basic spider, the coefficient of the result is either 0 or $\pm 1$.

We now define $[s_1 \hookrightarrow s_2] = \sum_{e \in L_1 \times L_2} (s_1 \cdot s_2)_e$ where $L_i$ is the set of legs of $s_i$. This bracket gives $LO_V$ the structure of a Lie algebra: antisymmetry of the bracket follows from antisymmetry of the symplectic form and the Jacobi identity is a consequence of associativity of composition in the operad.

1.2. Degree and symplectic action.

**Definition 1.2.** The degree of an $O$-spider is the number of legs minus 2.

Note that degree is additive under bracket. In particular, spiders of degree 0 based on the identity element of the operad $O$ generate a Lie subalgebra of $LO_V$, and spiders of positive degree generate another Lie subalgebra, denoted $hO_V$, or simply $hV$ if the operad is understood. The subalgebra generated by degree 0 spiders based on the identity element is isomorphic to $sp_V$, and it acts on $LO_V$ via the adjoint action, preserving degree. In particular, the action of $sp_V$ restricts to an action on $hV$.

The symplectic group $Sp_V$ also acts on $LO_V$ (and on $h_V$) by acting on the leg-labels. The elements of $LO_V$ which are fixed by the $Sp_V$-action are precisely those that are killed by the $sp_V$ action. These are called the invariants of the action.

The natural inclusion $V_n \hookrightarrow V_{n+1}$ induces an inclusion $h_n \hookrightarrow h_{n+1}$, and stabilizing as $n \to \infty$ one obtains $V_\infty = \lim_{\to} V_n$ and $h_\infty = \lim_{\to} h_n$.

We will be principally concerned with the homology of the positive degree subalgebra $h_\infty$ of $LO_\infty$ since in the cases $O = Lie$ and $O = Assoc$ it is the (primitive part of the $sp_\infty$-invariants of) this homology which computes the cohomology of $Out(F_n)$ and mapping class groups.

1.3. Chevalley-Eilenberg differential. The Lie algebra homology of $h_V$ is computed using the exterior algebra $\bigwedge h_V$ and the Chevalley-Eilenberg differential

$$
\partial_{\text{Lie}}(s_1 \wedge \ldots \wedge s_k) = \sum_{i < j} (-1)^{i+j+1} [s_i, s_j] \wedge s_1 \wedge \ldots \wedge \hat{s}_i \wedge \ldots \wedge \hat{s}_j \wedge \ldots \wedge s_k
$$

$$
= \sum_{i < j} \sum_{e \in L_i \times L_j} (-1)^{i+j+1} (s_i \cdot s_j)_e \wedge s_1 \wedge \ldots \wedge \hat{s}_i \wedge \ldots \wedge \hat{s}_j \wedge \ldots \wedge s_k
$$

Let $e = \{\lambda, \mu\}$ be any (unordered) pair of distinct spider legs. We may assume $\lambda \in s_i$ and $\mu \in s_j$ with $i \leq j$. To simplify notation in what follows, we define $X_e$ to be zero if $i = j$ and otherwise
\[ X_e = (-1)^{j+1}(s_i \cdot s_j)_e \wedge s_1 \wedge \ldots \wedge \hat{s}_i \wedge \ldots \wedge \hat{s}_j \wedge \ldots \wedge s_k \]

Then
\[ \partial_{\text{Lie}}(X) = \sum_{e \in E} X_e, \]
where \( e \) runs over all pairs \( \{\lambda, \mu\} \) of legs with \( \lambda \neq \mu \).

**Definition 1.3.** The degree of a wedge \( s_1 \wedge \ldots \wedge s_k \) is the sum of the degrees of the \( s_i \).

Since \( \partial_{\text{Lie}} \) preserves degree, \( \bigwedge h_V \) breaks up into a direct sum of chain complexes \( \bigwedge h_V(d) \) according to degree, and we define \( H_*(d)(h) \) to be the homology of this chain complex.

Since spiders can have any positive degree, the spaces of \( k \)-chains \( \bigwedge ^k h_V \) are generally not finite-dimensional, so the definition of cohomology becomes problematic. We resolve this using the observation that if \( V \) is finite-dimensional then there are only finitely-many ways to decorate the legs of a basic spider, so the degree \( d \) chains \( \bigwedge ^k h_V(d) \) are finite-dimensional.

**Definition 1.4.** If \( V \) is finite-dimensional, then the continuous cohomology \( H_*^c(h_V) \) is the cohomology computed from the cochain complex whose \( k \)-cochains are \( C^k h = \bigoplus _{d \geq 1}(\bigwedge ^d h_V(d))^* \).

If \( V \) is infinite-dimensional, we realize it as the direct limit of finite-dimensional subspaces \( V_n \) and choose projections \( V_n \to V_{n-1} \).

**Definition 1.5.** For \( V = \varinjlim _n V_n \), the continuous cohomology \( H_*^c(h_{V_\infty}) \) is the direct limit of the maps \( H_*^c(h_{V_{n-1}}) \to H_*^c(h_{V_n}) \) induced by the projections \( V_n \to V_{n-1} \).

### 1.4. Functoriality

One may regard \( \mathcal{LO} \) and \( h \) as (covariant) functors from the category of symplectic vector spaces to the category of Lie algebras. In particular, any linear map \( \phi : V \to W \) which respects the symplectic forms on \( V \) and \( W \) induces a Lie algebra homomorphism \( \phi_* : \mathcal{LO} V \to \mathcal{LO} W \), where the image of a spider is obtained by applying \( \phi \) to the labels. If \( \phi \) is injective (resp. surjective) then so is \( \phi_* \). The restriction \( \phi_* : h_V \to h_W \) to the positive degree subalgebras has the same properties. Thus, the natural inclusions \( V_n \hookrightarrow V_{n+1} \) induce inclusions \( \mathcal{LO} n \hookrightarrow \mathcal{LO} n+1 \) and \( h_n \hookrightarrow h_{n+1} \).

The functors \( \mathcal{LO} \) and \( h \) commute with direct limits. Since \( V_\infty = \bigcup _n V_n = \varprojlim _n V_n \) we also have that \( h_\infty = \varprojlim h_n \). The inclusions \( V_n \to V_{n+1} \) are chain maps, so since homology commutes with direct limits we have \( H_*(h_\infty) = \varprojlim H_*(h_n) \). In cohomology we have \( H_*^c(h_\infty) = \varprojlim H_*^c(h_n) \), since direct limits become inverse limits when we dualize.

The action of the symplectic group \( \text{Sp}_V \) commutes with the Lie bracket and hence with the Chevally-Eilenberg differential, so that \( \text{Sp}_V \) also acts on \( H_*(h_V) \) and \( H_*^c(h_V) \), and the association \( V \rightsquigarrow H_*(h_V) \) is a functor from symplectic vector spaces to symplectic modules. This functor preserves injections for infinite dimensional spaces:

**Lemma 1.6.** Let \( V \hookrightarrow W \) be an inclusion between two infinite-dimensional non-degenerate symplectic spaces. Then the induced map \( H_*(h_V) \to H_*(h_W) \) is injective.
Proof. We identify $V$ with its image in $W$ and $\wedge h_V$ with its image in $\wedge h_W$. We need to show that if a cycle $z \in \wedge h_V$ is a boundary in $\wedge h_W$, then is also a boundary in $\wedge h_V$.

Fix $x \in \wedge h_W$ with $\partial_{\text{Lie}}(x) = z$. Since $W$ and $V$ are direct limits we can find finite dimensional symplectic subspaces $V' \subseteq W'$ of $W$ such that $z \in \wedge h_V$ and $x \in \wedge h_W$. Since $V$ is infinite dimensional there exists a subspace $V''$ of $V$ containing $V'$ and a symplectic isomorphism $\pi : W' \to V''$ which is the identity on $V'$. Then $\pi_*(x) \in \wedge h_{V''} \subset \wedge h_V$ and $\partial_{\text{Lie}}(\pi_*(x)) = \partial_{\text{Lie}}(x) = \pi_*(z) = z$, since $\pi_*$ is the identity on $\wedge h_V$. \[\square\]

We remark that this proof does not work for finite-dimensional spaces $V$ and $W$.

2. The complex of hairy $\mathcal{O}$-graphs

Recall from [4] that a vertex $v$ of a graph was said to be $\mathcal{O}$-colored if the half-edges incident to $v$ are identified with the i/o slots of some element of $\mathcal{O}$. An $\mathcal{O}$-graph was then defined to be a graph which is oriented in the sense of Kontsevich and is $\mathcal{O}$-colored at every vertex. (Recall that an orientation of a graph is determined by ordering the vertices and orienting the edges). These $\mathcal{O}$-graphs $(G, o_r)$, modulo the relation $(G, o_r) = -(G, -o_r)$ plus linearity relations in the operad, span a chain complex which is isomorphic to the subcomplex of $\mathfrak{sp}_s$-invariants in $\wedge h_{\infty}$.

We may think of a (representative of an) $\mathcal{O}$-graph as something obtained from a wedge of spiders by taking the ordered disjoint union of these spiders, connecting their legs in pairs by oriented edges, and discarding the leg labels. In this section we define a more general complex, generated by (equivalence classes of) objects made by connecting only some pairs of legs by oriented edges and letting the rest of the legs keep their labels. We will call these hairy $\mathcal{O}$-graphs, i.e. a labeled leg is now to be thought of as a “hair.”

2.1. Chains. Hairy graphs will be based on graphs which are general 1-dimensional finite CW complexes; in particular these graphs may have multiple edges or loops, may be disconnected or have bivalent, univalent or isolated vertices.

Definition 2.1. A vertex $v$ of a graph is $\mathcal{O}/V$-tinted if the half-edges incident to $v$ are identified with a (possibly proper) subset of the i/o slots of an element $o_v$ of $\mathcal{O}$, and the remaining i/o slots $\lambda$ are labeled by vectors $x_{\lambda} \in V$. A hairy $\mathcal{O}$-graph $G = (G, o_r, \{o_v\}, \{x_{\lambda}\})$ is an oriented graph which is tinted at every vertex by an operad element with at least three i/o slots. Those legs which are labeled by $V$ will be called hairs.

If $V = V_n$ or $V_{\infty}$, all vertices are tinted by basis elements of $\mathcal{O}$ and all labels are in $\mathcal{B}$, the hairy graph is called a basic hairy $\mathcal{O}$-graph. A hairy $\mathcal{O}$-graph is called primitive if the underlying graph is connected.

We may also think of a hairy $\mathcal{O}$-graph as something obtained from a wedge of positive-degree $\mathcal{O}$-spiders by taking the ordered disjoint union of these spiders, connecting some of their legs in pairs by oriented edges and discarding those leg labels (retaining the labels on unpaired legs.)

We define $H_V$ to be the vector space spanned by hairy $\mathcal{O}$-graphs $(G, o_r, \{o_v\}, \{x_{\lambda}\})$, modulo orientation relations $(G, o_r, \{o_v\}, \{x_{\lambda}\}) = -(G, -o_r, \{o_v\}, \{x_{\lambda}\})$ plus linearity relations on the leg-labels $x_{\lambda}$ and the operad elements $o_v$. Then $H_V$ is graded by the number
HAIRY GRAPHS AND THE UNSTABLE HOMOLOGY OF \( \text{Mod}(g,s), \text{Out}(F_n) \) AND \( \text{Aut}(F_n) \)

of vertices:

\[ \mathcal{H}_V = \bigoplus_k C_k \mathcal{H}_V, \]

where \( C_k \mathcal{H}_V \) is spanned by hairy \( \mathcal{O} \)-graphs formed from \( k \) spiders, i.e., whose underlying graph \( G \) has \( k \) vertices.

Finally, we define \( \mathcal{P} \mathcal{H}_V \) to be the subspace of \( \mathcal{H}_V \) generated by connected hairy \( \mathcal{O} \)-graphs. Note that the correspondences \( V \rightsquigarrow \mathcal{H}_V \) and \( V \rightsquigarrow \mathcal{P} \mathcal{H}_V \) are functorial in \( V \). As before, if \( V = V_n \) or \( V = V_\infty \) we will denote the corresponding complexes by \( \mathcal{H}_n \), \( \mathcal{H}_\infty \), \( \mathcal{P} \mathcal{H}_n \), and \( \mathcal{P} \mathcal{H}_\infty \).

2.2. Boundary operator. We define a boundary operator \( \partial : C_k \mathcal{H}_V \to C_{k-1} \mathcal{H}_V \), which sums over all possible ways of using an edge to merge two operad elements. We need to be careful about the sign here, in order to make \( \partial^2 = 0 \). Details follow.

Suppose \( e \) is an edge of a hairy \( \mathcal{O} \)-graph \( G = (G \to, \{a_v\}, \{x_\lambda\}) \). Choose a representative of the orientation on \( G \) so that \( e \) is oriented from \( v_i \) to \( v_j \) with \( i \leq j \). If \( i = j \), define \( G_e = 0 \); otherwise define a new \( \mathcal{O} \)-graph \( G_e \) by the following procedure:

1. collapse the edge \( e \) to a single vertex,
2. fuse the operad elements tinting \( v_i \) and \( v_j \) into a single spider using the i/o slot corresponding to the initial half of \( e \) as output and the i/o slot corresponding to the terminal half of \( e \) as input,
3. number the vertices of the collapsed graph so that the resulting operad element tints the first vertex and the remaining vertices retain their relative order (and their tints),
4. multiply by \((-1)^{i+j+1}\).

Note that the sign convention imitates the sign in the Chevalley-Eilenberg boundary operator. The boundary operator \( \partial : C_k \mathcal{H}_V \to C_{k-1} \mathcal{H}_V \) is then defined by

\[ \partial(G) = \sum_{e \in E(G)} G_e, \]

where \( E(G) \) is the set of oriented edges of \( G \). It is straightforward to check that this is well-defined, and that \( \partial \circ \partial = 0 \).

Remark 2.2. Note that the boundary operator makes no use of the symplectic form on \( V \). For any linear map \( \phi : V \to W \), it is clear that the induced map \( \phi_* : \mathcal{H}_V \to \mathcal{H}_W \) commutes with the differential \( \partial \) so that there is an induced map \( \phi_* : H_*(\mathcal{H}_V) \to H_*(\mathcal{H}_W) \). Thus \( V \rightsquigarrow \mathcal{H}_V \) (resp. \( V \rightsquigarrow H_*(\mathcal{H}_V) \)) are functors from the category of vector spaces to the category of complexes (resp. graded vector spaces).

2.3. Gradings on \( \mathcal{H}_V \). There are several different things to count in a hairy graph, and we will have occasion to use different ones at various points in this paper. The most important of these is the degree of a hairy graph \( G \), which is defined to be sum of the degrees of the spiders tinting the vertices. Recall that we required these degrees to be positive, so that there are no hairy graphs of degree 0. The boundary operator \( \partial \) preserves degree, so that \( \mathcal{H}_V \) breaks up as a direct sum of subcomplexes \( \mathcal{H}_V(d) \) according to degree. Note that if
V is finite-dimensional, then $\mathcal{H}_V(d)$ is also finite-dimensional, since there are only finitely many graphs of a given degree.

Other things we can count include:

1. The number of edges in the underlying oriented graph $G$. The boundary operator decreases this by one.
2. The number of hairs (i.e., labeled legs) in $G$. The boundary operator preserves this.
3. The rank of the fundamental group of a primitive (i.e., connected) $G$, which we call the rank of $G$. The boundary operator preserves this.

2.4. Homology. Recall that an inclusion $V \hookrightarrow W$ of symplectic vector spaces is only guaranteed to induce an injection $H_\ast(h_V) \rightarrow H_\ast(h_W)$ if $V$ and $W$ are infinite-dimensional and non-degenerate (Lemma 1.6). An advantage of the hairy graph homology functor is that it ignores the symplectic form, so is better behaved:

**Lemma 2.3.** The functor $V \rightsquigarrow H_\ast(h_V)$ preserves injections and surjections.

**Proof.** Let $i: V \hookrightarrow W$ be an inclusion of vector spaces. Since every subspace has a complement we can find a projection $p: W \rightarrow V$ such that the composition $p \circ i$ is the identity. Applying the functor to this map gives

\[
\begin{array}{ccc}
V & \overset{i}{\longrightarrow} & W \\
\downarrow p & & \downarrow \\
V & \overset{i_\ast}{\longrightarrow} & H_\ast(h_W) \\
& & \overset{p_\ast}{\longrightarrow} \\
& & H_\ast(h_V)
\end{array}
\]

By functoriality we have that $p_\ast \circ i_\ast = (\text{Id})_\ast = \text{Id}$ therefore $i_\ast$ is injective.

The proof that the functor preserves surjections is similar. □

**Remark 2.4.** The reason this proof does not work for $H_\ast(h_V)$ is that there is generally no projection $p: W \rightarrow V$ which preserves the symplectic form, so there is no induced map $H_\ast(h_W) \rightarrow H_\ast(h_V)$. In category-theoretic language, not every object is projective (or injective) in the category of symplectic vector spaces.

3. The Trace map

There is an obvious inclusion $\iota: \wedge h_V \rightarrow \mathcal{H}_V$, which sends a wedge $X$ to an $O$-graph with no oriented edges, i.e., it simply erases the wedge symbols, keeping the ordering of the spiders. However, this is not a chain map: the differential $\partial_{\mathcal{H}}$ is zero on the image, but the Chevalley-Eilenberg differential is not zero. In this section we define a new map $\text{Tr}_V: \wedge h_V \rightarrow \mathcal{H}_V$, which is a chain map. Basically, the map $\text{Tr}_V$ sums over all possible ways to match spider legs to form an $O$-graph. Unless we need to specify the vector space $V$, we will denote the trace map simply by $\text{Tr}$.

**Definition 3.1.** Let $G = (G, \text{or}, \{o_v\}, \{x_\lambda\})$ be a hairy $O$-graph, with legs (equivalently, hairs) $L = L(G)$. A matching $M$ is a partition of a subset of $L$ into pairs.
Given a matching $M$, let $G^M$ denote the element of $\mathcal{H}$ obtained by

1. connecting each pair of legs $\{\lambda, \mu\} \in M$ with an oriented edge from $\lambda$ to $\mu$,
2. erasing the labels $x_\lambda$ and $x_\mu$, and
3. multiplying the result by the product $\prod \omega(x_\lambda, x_\mu)$

Note that $G^M$ is a well-defined element of $\mathcal{H}_V$. In particular, it doesn’t matter whether we orient an edge from $\lambda$ to $\mu$ and multiply by $\omega(x_\lambda, x_\mu)$ or orient it from $\mu$ to $\lambda$ and multiply by $\omega(x_\mu, x_\lambda)$.

For $X = s_1 \wedge \ldots \wedge s_k$, we define

$$\text{Tr}(X) = \sum_M (\iota X)^M$$

where $M$ runs over all possible matchings of the legs of the spiders $s_i$. The map $\text{Tr}$ can also be described as

$$\text{Tr}(X) = \exp(T)(\iota X) = \iota X + T(\iota X) + \frac{1}{2!}T^2(\iota X) + \frac{1}{3!}T^3(\iota X) + \ldots,$$

where $T: \mathcal{H}_V \to \mathcal{H}_V$ matches exactly two legs in all possible ways, i.e.

$$T(G) = \sum_{|M|=2} G^M.$$

(see Figure 1). Note that both $T$ and $\exp(T)$ preserve degree, and that neither $T$ nor $\exp(T)$ is a chain map.

**Proposition 3.2.** $\text{Tr}$ is a chain map.

**Proof.** We need to show $\partial_\mathcal{H} \circ \text{Tr} = \text{Tr} \circ \partial_{\mathcal{H}_{\text{Lie}}}$. A pair of spider-legs $\{\lambda, \mu\}$ is called internal if they are on the same spider, and external if they are on different spiders. Applying $\text{Tr}$ sums over all possible matchings; then applying $\partial_\mathcal{H}$ sums over all ways of fusing a single external pair from each matching. On the other hand $\partial_{\mathcal{H}_{\text{Lie}}}$ sums over all ways of matching one external pair and fusing it; applying $\text{Tr}$ then gives all possible ways of matching remaining sets of legs. In either case, the result is the sum of all matchings with one external pair fused. The signs defining $\partial_{\mathcal{H}_{\text{Lie}}}$ and $\partial_\mathcal{H}$ are designed to agree. \qed

In the sequel we will give a more conceptual explanation of why $\text{Tr}$ is a chain map.

The main reason for studying the hairy graph complex $\mathcal{H}_\infty$ is to be able to get information about $H_*(\mathcal{H}_\infty)$ through knowledge of $H_*(\mathcal{H}_\infty)$. The following theorem, in combination
with Theorem 3.6, allows us to do this. In the sequel, we will analyze the case of finite $n$, showing that $\Tr$ is “almost” injective.

**Theorem 3.3.** \( \Tr_\infty \) induces an injection \( H_*(H_\infty) \to H_*(H_\infty) \).

We would like to prove the theorem by defining chain maps \( \beta_n : H_n \to \wedge h_n \) and proving that \( \beta_n \circ \Tr_n(X) = X \), so that \( \beta_n \circ \Tr_n \) induces the identity on homology for all \( n \). The map \( \exp(-T) : H \to H \) is an inverse to \( \exp(T) \), so we just need a map \( \alpha \) which breaks up a hairy \( O \)-graph into \( O \)-spiders in such a way that \( \beta_n = \alpha \circ \exp(-T) \) is a chain map. This almost works, but not quite; it turns out that \( \Tr_n \) may not induce an injection \( H_*(h_n) \to H_*(H_n) \) for finite \( n \), but only becomes injective after stabilization. To prove injectivity we must therefore be slightly devious when defining \( \alpha \).

Any basic hairy \( O \)-graph \( G \) is equal to \( \langle \iota X \rangle^M \) for some wedge \( X \) of basic spiders and some matching \( M \). Then \( \exp(-T)(G) \) is given by the formula

\[
\exp(-T)(G) = \sum_{M' \geq M} (-1)^{m' - m} \langle \iota X \rangle^{M'}.
\]

where the sum is over all matchings \( M' \) containing \( M \) (or, equivalently, the sum over all matchings of the legs of \( G \)), \( m \) is the size of \( M \) and \( m' \) is the size of \( M' \).

We want a map \( \alpha \) which cuts apart each hairy \( O \)-graph into a wedge of \( O \)-spiders, labels the cut edges with new labels which are distinct from the old labels, and multiplies the matchings of the legs of \( M \) in such a way that \( \beta_n = \alpha \circ \exp(-T) \) is a chain map. We will define \( \alpha \) separately on the degree \( d \) subcomplexes \( H_V(d) \), writing \( \alpha_{d,V} \) for the restriction of \( \alpha \) to \( H_V(d) \).

A hairy \( O \)-graph \( G \) of degree \( d \) has at most \( 3d \) free legs, so any matching of its free legs has at most \( \lfloor \frac{3d}{2} \rfloor \) elements. Set \( N = \lfloor \frac{3d}{2} \rfloor \), and fix a new \( 2N \)-dimensional vector space \( W_d \) with symplectic basis \( B' = \{ p'_1, q'_1, \ldots, p'_N, q'_N \} \). The target of \( \alpha_{d,V} \) will be the exterior product \( \wedge h_{V \oplus W_d}(d) \) instead of \( \wedge h_V(d) \), i.e. the labels on spider legs are allowed to be in \( V \oplus W_d \).

For \( G = \langle \iota X \rangle^M \in H_V(d) \), define a state \( s \) of \( M \) to be an assignment of new labels from \( B' \) to the legs in \( M \) such that

1. the labels on each pair in \( M \) are dual, i.e. they are \( p'_i \) and \( q'_i \) for some index \( i \) with \( 1 \leq i \leq N \)
2. the indices for different pairs in \( M \) are distinct.
3. replacing the original labels of \( X \) on legs in \( M \) by the labels in \( s \) results in a new wedge, denoted \( X \{ s \} \), with \( \langle \iota X \{ s \} \rangle^M = \pm G \).

Let \( S(M) \) denote the set of all possible states of \( M \). The number of such states is

\[
|S(M)| = 2N(2N-2)(2N-4) \ldots (2N-2m+2) = 2^m N! / (N-m)!.
\]

We define the sign of a state to be \( \sigma(s) = 1 \) if \( \langle \iota X \{ s \} \rangle^M = G \) and \( \sigma(x) = -1 \) if \( \langle \iota X \{ s \} \rangle^M = -G \). We now define \( \alpha_{d,V} : H_V(d) \to \wedge h_{V \oplus W_d}(d) \) by summing over all possible
states, normalized by the number of possible states:

\[
\alpha_{d,V}(\iota X^M) = \frac{1}{|S(M)|} \sum_{s \in S(M)} \sigma(s) X\{s\} = \frac{(N - m)!}{2^m N!} \sum_{s \in S(M)} \sigma(s) X\{s\}.
\]

**Lemma 3.4.** \(\beta_{d,V} = \alpha_{d,V} \circ \exp(-T) : H_V(d) \to \wedge h_{V\otimes W}(d) \) is a chain map.

**Proof.** To simplify notation we will identify \(\wedge h_V\) with its image (under \(\iota\)) in \(H_V\) so that \((\iota X)^M\) becomes \(X^M\).

We first compute \(\beta_{d,V} \partial_{\mathcal{H}}(X^M)\):

\[
\beta_{d,V} \partial_{\mathcal{H}}(X^M) = \beta_{d,V} \sum_{e \in M} X\{e\}^M
\]

\[
= \alpha_{d,V} \sum_{e \in M} \sum_{M' \supseteq M} (-1)^{m' - m} X\{e\}^M'
\]

\[
= \sum_{e \in M} \sum_{M' \supseteq M} (-1)^{m' - m} \frac{1}{|S(M' - e)|} \sum_{s \in S(M' - e)} \sigma(s) X\{s\}.
\]

On the other hand,

\[
\partial_{\text{Lie}} \beta_{d,V}(X^M) = \partial_{\text{Lie}} \alpha_{d,V} \sum_{M' \supseteq M} (-1)^{m' - m} X\{e\}^M'
\]

\[
= \partial_{\text{Lie}} \sum_{M' \supseteq M} (-1)^{m' - m} \frac{1}{|S(M')|} \sum_{s \in S(M')} \sigma(s) X\{s\}
\]

\[
= \sum_{M' \supseteq M} (-1)^{m' - m} \frac{1}{|S(M')|} \sum_{s \in S(M')} \sigma(s) X\{s\}
\]

\[
= \sum_{e \in E} \sum_{M' \supseteq M} (-1)^{m' - m} \frac{1}{|S(M')|} \sum_{s \in S(M')} \sigma(s) X\{s\},
\]

where \(E\) is the set of pairs of distinct legs of \(X\).

The lemma now follows from the following two observations:

1. If \(e \in M\), then \(\frac{1}{|S(M')|} \sum_{s \in S(M')} \sigma(s) X\{s\} = \frac{1}{|S(M' - e)|} \sum_{s \in S(M' - e)} \sigma(s) X\{s\}\).

2. If \(e \not\in M\), then the terms \((-1)^{m' - m} \frac{1}{|S(M')|} \sum_{s \in S(M')} \sigma(s) X\{s\}\) cancel.

Both observations are true because each time the term \(\sigma(s) X\{s\}\) arises from a matching \(M'\) containing \(e\) it occurs \(2(N - (m' - 1))\) times, but it also arises once from the matching \(M' - e\) with opposite sign.

\(\Box\)

Returning to the functorial perspective, we have the following lemma.

**Lemma 3.5.** The family of maps \(\text{Tr}_{V}\) and \(\beta_{d,V}\) form natural transformations between the functors \(\wedge h_{-}(d) \leadsto H_{-}(d)\) and \(H_{-}(d) \leadsto \wedge h_{-\otimes W}(d)\) respectively.
Proof. Let \( \phi : V \to V' \) be a linear map which preserves the symplectic form. The naturality of \( \text{Tr} \) and \( \beta \) is equivalent to commutativity of the diagrams

\[
\begin{array}{ccc}
\bigwedge h_V(d) & \xrightarrow{\phi_*} & \bigwedge h_{V'}(d) \\
\downarrow \text{Tr}_V & & \downarrow \text{Tr}_{V'} \\
\bigwedge h_{V'}(d) & \xrightarrow{\phi_*} & \bigwedge h_{V'}(d)
\end{array}
\]

\[
\begin{array}{ccc}
\bigwedge h_V(d) & \xrightarrow{\phi_*} & \bigwedge h_V(d) \\
\downarrow \beta_{d,V} & & \downarrow \beta_{d,V'} \\
\bigwedge h_{V'}(d) & \xrightarrow{\phi_*} & \bigwedge h_{V'}(d)
\end{array}
\]

i.e., \( \phi_* \circ \text{Tr}_V = \text{Tr}_{V'} \circ \phi_* \) and \( \phi_* \circ \beta_{d,V} = \beta_{d,V'} \circ \phi_* \). The commutativity of these diagrams follows immediately from the definitions of the maps \( \text{Tr} \) and \( \beta \).

\[\square\]

Proof of Theorem 3.3. For any \( V \) we have

\[\beta_{d,V}(\text{Tr}(X)) = \alpha_{d,V}(\exp(-T)(\exp(T)(\iota X))) = \alpha_{d,V}(\iota X).\]

But \( \iota X \) is an \( O \)-graph with no oriented edges, so \( \alpha \) has no edges to break and we just have \( \alpha_{d,V}(\iota X) = X \). In particular, for \( V = V_\infty \) we have \( \beta_{d,\infty} \text{Tr}_\infty \) is just the inclusion \( \bigwedge h_\infty(d) \hookrightarrow \bigwedge h_{V_\infty \oplus W_\infty}(d) \). By Lemma 1.6, this inclusion induces an injection on homology, which implies that \( \text{Tr}_\infty : H_* \bigwedge h_\infty(d) \to H_*(\bigwedge h_\infty(d)) \) is injective. Since the complexes \( \bigwedge h_\infty \) and \( \bigwedge h_\infty \) break up as direct sums according to degree \( d \), we have that \( \text{Tr}_\infty : \bigwedge h_\infty \to \bigwedge h_\infty \) is injective on homology.

Since \( \text{Tr}_\iota \) is injective, computing \( H_*(\bigwedge h_\infty) \) gives us a sort of “upper bound” on \( H_*(\bigwedge h_\infty) \). The next theorem gives a complementary “lower bound.”

Let \( V_n^+ \subset V_n \) be the subspace spanned by \( \{p_1, \ldots, p_n\} \), and \( V_\infty^+ \subset V_\infty \) the union of all the \( V_n^+ \). Let \( H^+_\infty \subset H_\infty \) be the subcomplex spanned by hairy graphs with all labels in \( V_\infty^+ \). The projection \( p : H_\infty \to H^+_\infty \) sending a hairy \( O \)-graph \( G \) to itself if all labels are in \( V_\infty^+ \) and to zero otherwise is clearly a surjective chain map.

**Theorem 3.6.** The composition \( H_*(\bigwedge h_\infty) \xrightarrow{\text{Tr}_\iota} H_*(\bigwedge h_\infty) \xrightarrow{p_*} H_*(H^+_\infty) \) is surjective.

Proof. Since the complexes \( \bigwedge h_\infty \) and \( H_\infty \) break up as direct sums according to degree \( d \), it suffices to show this separately for each \( d \).

Any cycle \( z \) in \( H^+_\infty(d) \) is a sum of hairy graphs \( G \), all of whose labels are in \( V_n^+ \subset V_\infty^+ \) for some \( n \). Then \( z \) is also a cycle in \( H_n(d) \), and since \( \beta_{d,n} \) is a chain map \( \beta_{d,n}(z) \) is a cycle in \( \bigwedge h_n \oplus W_d(d) \). Choose an isomorphism of \( W_d \) with a subspace of \( V_\infty \) which sends each \( \{p_j', q_j'\} \) to \( \{p_j, q_j\} \) for some \( j > n \), and apply this isomorphism to the labels of \( \beta_{d,n}(z) \) which are in \( W_d \). The result is still a cycle \( \tilde{\beta}_{d,n}(z) \) but is now in \( \bigwedge h_\infty \). We claim that the image of this cycle under \( \text{Tr} \circ p \) is equal to \( z \).

Since the symplectic product is zero on the labels of \( z \), \( \exp(-T)(z) = z \), so \( \beta_{d,n}(z) = \alpha_{d,n}(z) \). Now \( \alpha_{d,n}(z) \) is obtained by breaking all edges of graphs in \( z \) and labeling the resulting legs by labels in \( W_d \). In \( \tilde{\beta}_{d,n}(z) \) the labels in \( W_d \) are replaced by labels in \( V_\infty \). We now apply \( \text{Tr} = \exp(T) \iota \) to \( \tilde{\beta}_{d,n}(z) \). The only matchings of \( \iota \tilde{\beta}_{d,n}(z) \) which give nonzero terms when we apply \( \exp(T) \) are those which originally came from edges of \( z \). The
projection $p$ then kills all terms of $\text{Tr}(\tilde{\beta}_{d,n}(z))$ except the term which rematches all of the edges of $z$. In other words, $p(\text{Tr}(\tilde{\beta}_{d,n}(z))) = z$. Since every cycle is in the image of $p \circ \text{Tr}$, the induced map on homology is surjective.

Since $H_*(\mathcal{H}_\infty^+)$ generates $H_*(\mathcal{H}_\infty)$ as a $\text{GL}(V_\infty)$-module, Theorem 3.6 shows that the image of $\text{Tr}^*$ is at least large. In the sequel to this paper, we will give a different description of the image of $\text{Tr}^*$ by defining a certain operator on $\mathcal{H}_\infty$ and using representation theory to prove that the kernel of this operator is a subcomplex which computes this image exactly.

4. Schur functors and the image of $\text{Tr}^*$

We have defined several functors from the category of vector spaces to itself. By classical representation theory any such functor can be decomposed as a direct sum of Schur functors $S_\lambda$ indexed by partitions $\lambda$. The $S_\lambda V$ are called Weyl modules; they are irreducible representations of $\text{GL}(V)$, if the dimension of $V$ is sufficiently large. The module $S_\lambda V$ can be defined using the irreducible representation $P_\lambda$ of the symmetric group $S_n$ corresponding to the partition $\lambda$ via

$$S_\lambda V = P_\lambda \otimes S_n V^\otimes n,$$

where the symmetric group acts on the tensor power $V^\otimes n$ by permuting the factors. If $\lambda = (k)$ is the trivial partition of $k$, then $S_\lambda V$ is the $k$-th symmetric power $S^k V$, and if $\lambda = (1, 1, \ldots, 1)$ then $S_\lambda V$ is the $k$-th exterior power $\wedge^k V$. If $\dim(V) = n$ and $\lambda = (m, k - m)$, then

$$\dim S_{(m,k-m)}(V) = \frac{2m - k + 1}{m + 1} \binom{n - 2 + (k - m)}{k - m} \binom{n + m - 1}{m}.$$  

In general if $\lambda$ is a partition of $k$, then $S_\lambda V$ is the image of the action of the Young symmetrizer $c_\lambda \in \mathbb{k}[\Sigma_k]$ on $V^\otimes k$ (see, e.g. [7]).

If the vector space $V$ has a symplectic structure then $S_\lambda V$ is also a representation of $\text{Sp}(V)$, but is not necessary an irreducible representation. It does have a large irreducible component denoted by $S_\lambda V$. If $V^+$ is any Lagrangian subspace of $V$, then $S_\lambda V$ is generated as an $\text{Sp}(V)$-module by $S_\lambda V^+$. Applying this to functor giving the degree $d$ component of $H_*(\mathcal{H}_V)$, we decompose

$$H_*(\mathcal{H}_V(d)) = \bigoplus (S_\lambda V)^{\oplus m_{d, \lambda}}$$

and

$$\text{Sp}(V) \cdot H_*(\mathcal{H}_V^+(d)) = \bigoplus (S_\lambda V)^{\oplus m_{d, \lambda}}$$

In all examples we have computed, $\text{Sp}(V) \cdot H_*(\mathcal{H}_V^+(d))$ coincides with $\text{im} \text{Tr}^*$, and we conjecture that this is true in general.

5. $H_1(\mathcal{H})$ and $\mathfrak{h}^{AB}$ for the commutative operad

Recall that the commutative operad $\text{Com}((n)) = \mathbb{k}$ for all $n \geq 2$, with all compositions induced by multiplication in $\mathbb{k}$. In this case all of the constructions we have given are very simple, especially in dimension 1. We go through them here as a warm-up exercise.
5.1. **The commutative Lie algebra.** Basic commutative spiders can be thought of as star graphs, i.e. connected graphs with one central vertex and all other vertices univalent, labeled by basis elements of \( V \). Two spiders are fused by identifying a leg of one spider with a leg of the other, then collapsing this leg and multiplying the result by the symplectic product of the leg labels. In terms of Schur functors, for all \( d \), the functor \( V \xrightarrow{\sim} \mathcal{L}\text{Com}_V(d) \) is simply

\[
\mathcal{L}\text{Com}_V(d) \cong S_{(d+2)} V \cong S^{d+2} V,
\]

where both sides of the isomorphism are regarded as \( \text{GL}(V) \)-modules.

5.2. **Commutative hairy graph homology in dimension 1.** A hairy graph is just a finite graph with no bivalent vertices, whose univalent vertices are labeled by elements of \( V \). Since there are no hairy graphs with 0 vertices \( C_0 \mathcal{H} = 0 \) and the first homology of \( \mathcal{H} \) is the quotient of \( C_1 \mathcal{H} \) by the image of \( \partial_\mathcal{H} : C_2 \mathcal{H} \to C_1 \mathcal{H} \). The generators of \( C_1 \mathcal{H} \) are hairy graphs \( G \) with one vertex. If this vertex \( v \) has valence at least 4, then the half-edges at \( v \) can be partitioned into two sets, each of size at least 2, such that no oriented edge has both its half-edges in the same piece of the partition. We can use this partition to blow up \( v \) into an oriented edge \( e \) in a new hairy graph \( G' \); then the boundary map just collapses \( e \), and \( \partial_\mathcal{H} G' = G \). If \( v \) has valence 3, then \( G \) cannot be in the image of \( \partial_\mathcal{H} \) because \( \partial_\mathcal{H} \) preserves degree, and there are no graphs in \( C_2 \mathcal{H} \) of degree 1. Therefore \( H_1(\mathcal{H}) \) is generated by tripods and loops with one hair. The labels on the hairs in each case give an isomorphism

\[
H_1(\mathcal{H}) \cong H_1(\mathcal{H})(1) \cong S^3 V \oplus V = S_{(3)} V \oplus V.
\]

5.3. **The abelianization of \( \mathfrak{h} \).** The trace of a basic degree 1 spider in \( \mathfrak{h} \) is either a tripod (if all symplectic pairings on its labels are 0), a tripod plus a graph with one loop and one hair (if there is one non-zero pairing), or a tripod plus twice a one-loop, one-hair graph (if there are two non-zero pairings). Thus the image of the trace map is isomorphic to one copy of \( S^3 V \):

\[\mathfrak{h}^{ab} \cong \text{im}(\text{Tr}_*) \cong S^3 V.\]

6. **\( H_1(\mathcal{H}) \) and \( \mathfrak{h}^{ab} \)** **FOR THE ASSOCIATIVE OPERAD**

For the associative operad, \( \text{Assoc}((n)) \) is the \( k \)-vector space with basis given by all cyclic orders of \( \{1, \ldots, n\} \). Compositions are induced by amalgamating two cyclic orders consistently into one.

The computations of \( H_1(\mathcal{H}) \) and \( \mathfrak{h}^{ab} \) are more subtle than in the commutative case, but the basic plan is the same: we first compute the hairy graph homology \( H_1(\mathcal{H}) \) then compute the abelianization \( \mathfrak{h}^{ab} \) by determining its image under \( \text{Tr}_* \) in \( H_1(\mathcal{H}) \). The computation illustrates the power of the trace map \( \text{Tr}_* \), allowing us to show that the abelianization is mostly trivial with relative ease. The abelianization has one piece in degree 1 and one piece in degree 2 (computed by Morita [21]) but vanishes for all higher degrees. We remark that in Morita’s paper [21], the Lie algebra \( \mathfrak{h} \) is denoted by \( \mathfrak{a}^+ \).
6.1. The associative Lie algebra. Basic associative spiders are now planar star graphs, i.e. connected planar trees with one central vertex and all other vertices univalent and labeled by elements of $V$. The planar embedding can be thought of as a cyclic ordering on the edges. Two Assoc-spiders are fused by identifying two univalent vertices, collapsing the adjacent edges and then multiplying the result by the symplectic product of the associated labels. For all $d$ we have $\mathcal{L}_{\text{Assoc}}(d) \cong [V^\otimes d+2]/\mathbb{Z}_{d+2}$, the quotient of $V^\otimes d+2$ by the cyclic action which permutes the factors. In terms of Schur functors, for small $d$ this decomposes as

- $\mathcal{L}_{\text{Assoc}}(0) \cong S(2)V$
- $\mathcal{L}_{\text{Assoc}}(1) \cong S(3)V \oplus S(1,1,1)V$
- $\mathcal{L}_{\text{Assoc}}(2) \cong S(4)V \oplus S(2,2)V \oplus S(2,1,1)V$
- $\mathcal{L}_{\text{Assoc}}(3) \cong S(5)V \oplus S(3,2)V \oplus 2S(3,1,1)V \oplus S(2,2,1)V \oplus S(1,1,1,1)V$

6.2. Associative hairy graph homology in dimension 1. The 1-chains $C_1\mathcal{H}$ are generated by hairy graphs $G$ with one vertex. The boundary map on $C_1\mathcal{H}$ is zero, so all elements are cycles, and the first homology of $\mathcal{H}$ is the quotient of $C_1\mathcal{H}$ by the image of the boundary operator $\partial_2: C_2\mathcal{H} \to C_1\mathcal{H}$. We begin with some observations about the image of $\partial_2$.

**Definition 6.1.** A vertex $v$ of a planar graph $G$ is a planar cut vertex if the half-edges adjacent to $v$ can be partitioned into two sets, each with at least two elements and each contiguous in the cyclic ordering, in such a way that there is no path in the graph $G - v$ from a point in one set to a point in the other. (see Figure 2a).

For example, if $G$ is not a tripod and $G$ has two adjacent hairs at $v$, then $v$ is a planar cut vertex.

**Lemma 6.2.** Let $G$ be a generator of $C_1\mathcal{H}$, with central vertex $v$. If $v$ is a planar cut vertex, then $G$ is in the image of $\partial_2$.

**Proof.** Since $v$ is a planar cut vertex it can be blown up into a separating edge in a new Assoc-graph $G'$. Then $G = \partial_2(G')$. \qed

**Lemma 6.3.** Let $G$ be a generator of $C_1\mathcal{H}$. If $G'$ is obtained from $G$ by sliding a half-edge at one end of an oriented edge of $G$ along the edge to the other end, then $G'$ is homologous to $G$.

**Proof.** Midway through the slide we have a 2-vertex $O$-graph with two oriented edges between its vertices, whose boundary is the difference of the original $O$-graph and the $O$ graph obtained by sliding (see Figure 2b). Thus modulo boundaries, the two $O$-graphs are the same. \qed

**Theorem 6.4.** For $O = \text{Assoc}$, $H_1(\mathcal{H})(1)$ is generated by tripods and loops with one hair, $H_1(\mathcal{H})(2)$ is generated by loops with two hairs on opposite sides of the loop, and $H_1(\mathcal{H})(d) = 0$ for $d > 2$. As $\text{GL}(V)$-modules, we have

- $H_1(\mathcal{H})(1) \cong S(3)V \oplus S(1,1,1)V \oplus V$
- $H_1(\mathcal{H})(2) \cong S(1,1)V$
Proof. The cyclic orderings at the vertices of an $O$-graph $G$ give $G$ a ribbon graph structure, so that $G$ can be “fattened” to an oriented surface with boundary. If two hairs are attached to a single boundary component of this fat graph, then unless $G$ is a tripod, the hairs can be slid using Lemma 6.3 to be adjacent, so that $G$ is a boundary by Lemma 6.2. Thus we may assume $G$ has at most one hair attached to each boundary component. If $G \in C_1 \mathcal{H}$, then again using Lemma 6.3 we may perform handle slides to get a standard fat graph description of a genus $g$ surface with $k$ boundary components: $G$ is a wedge product of $g$ pairs of dual edges and $k-1$ circles, possibly with hairs attached. Thus the central vertex of $G$ is a planar cut vertex unless $g = k = 1$, or $g = 0$ and $k \in \{1, 2\}$.

If $g = k = 1$ then $G$ has an orientation reversing automorphism as described in [2]; this occurs even if there is a hair attached (modulo boundaries). Thus $G$ is trivial in $\mathcal{H}$.

If $g = 0$, then $G$ is either a tripod or a single oriented loop with either 1 or 2 hairs attached. If $G$ has 2 hairs, one is inside the loop and one is outside. Such a $G$, with one hair inside and one hair outside the loop, is a nontrivial homology class. For if $G = \partial \mathcal{H} G'$, $G'$ would have to contain a graph which expands the 4-valent vertex of $G$ into an edge. There is one such graph up to isomorphism, and it has trivial boundary. Thus $\partial \mathcal{H} G' \neq G$.

If $G$ is a single oriented loop with 1 hair it cannot be the boundary of anything since the vertex is trivalent, so it also represents a non-trivial element of $H_1(\mathcal{H})$.

The non-trivial classes which are represented by loops with 2 hairs form a copy of $\wedge^2 V$. The antisymmetry comes from the involution which rotates the 4-valent vertex to exchange the hairs, switching the edge orientation in the process. The classes represented by tripods correspond naturally to $V^\otimes 3$ modulo the cyclic action of $\mathbb{Z}_3 = \mathbb{Z}/3\mathbb{Z}$. The graph with one loop and one hair gives a copy of $V$. Thus we have shown $H_1(\mathcal{H}) \cong (V^\otimes 3)_{\mathbb{Z}/3\mathbb{Z}} \oplus V \oplus \wedge^2 V$, with the first two summands in degree 1 and the second in degree 2.

\[\square\]

6.3. The abelianization of $\mathfrak{h}$. In [21], Morita computes that the degree 2 part of the abelianization of $\mathfrak{h}$ is isomorphic to $(\wedge^2 V)/\mathbb{I}\omega_0$, where $\omega_0 = \sum_i p_i \wedge q_i$. We use this together with the trace map to determine the complete abelianization of $\mathfrak{h}$:

**Theorem 6.5.** For $O = \text{Assoc}$,

$$\mathfrak{h}^{ab} \cong [V^\otimes 3]_{\mathbb{Z}_3} \oplus (\wedge^2 V)/\mathbb{I}(\omega_0)$$

where $\omega_0 = \sum_i p_i \wedge q_i$.

**Proof.** The map $\text{Tr}_* \mathfrak{h}$ is injective, so to determine $\mathfrak{h}^{ab}$ it suffices to calculate the image $\text{Tr}_* \mathfrak{h}^{ab}$ in $H_1(\mathcal{H})$. The trace map preserves degree, so we do this for degree 1 and 2 separately.

The degree 1 part of $\mathfrak{h}$ consists of spiders with three legs, and all of these represent nontrivial elements of the abelianization, since everything in the image of the bracket has at least four legs. Thus the degree 1 part of $\mathfrak{h}^{ab}$ is isomorphic to $[V^\otimes 3]_{\mathbb{Z}_3}$.

The degree 2 part of $\mathfrak{h}$ contains 4-legged spiders with labels $a, p_N, b, q_N$ arranged cyclically, where $\omega(p_N, q_N) = 1$ is the only non-zero pairing. On the level of homology, the trace of such a spider is equal to the loop with two hairs (representing $a \wedge b$), since the other
HAIRY GRAPHS AND THE UNSTABLE HOMOLOGY OF $\text{Mod}(g, s)$, $\text{Out}(F_n)$ AND $\text{Aut}(F_n)$

\[ \partial_H \]

\[ \text{(a)} \]

\[ \partial_H = \]

\[ \text{(b)} \]

**Figure 2.** (a) Degree 1 graphs with planar cut vertices are null-homologous. (b) Two degree 1 graphs related by handle slide are homologous.

The term (the spider by itself) is null-homologous. Thus the entire kernel of $\omega: \wedge^2 V \to k$ is in the image of $\text{Tr}_s$, and we have

\[ \text{im}(\text{Tr}_s) \supset \ker(\omega) \cong \wedge^2 V / k(\omega_0). \]

The fact that the image cannot be any larger can be argued by hand or by appealing to Morita’s calculation of the degree 2 piece.

\[ \square \]

7. $H_1(\mathcal{H})$ FOR THE LIE OPERAD

The Lie operad has $\mathcal{L}ie((n))$ spanned by planar uni-trivalent trees with $n$ leaves distinctly labeled by $\{0, \ldots, n - 1\}$, modulo the Jacobi identity (IIHX relation) and antisymmetry relations. Composition is induced by joining two trees at univalent vertices.

7.1. **The Lie Lie algebra.** We can represent a basic Lie spider by drawing a planar unitrivalent tree and labeling its leaves with basis elements $v \in \mathcal{B}$. Two Lie spiders are fused by joining a leg of the first spider to a leg of the second and multiplying the result by the symplectic product of the associated leg labels. In terms of Schur functors, for small values of $d$ we have

- $\mathcal{L}ie_V(0) \cong S(2)V$
- $\mathcal{L}ie_V(1) \cong S(1,1)V$
- $\mathcal{L}ie_V(2) \cong S(2,2)V$
- $\mathcal{L}ie_V(3) \cong S(3,1,1)V$

7.2. **Hairy Lie graph homology in dimension 1.** A hairy Lie graph is represented by an ordered disjoint union of Lie spiders, with some leaves joined by oriented edges and unlabeled. See Figure 3.

In [4], it was shown that the Lie graph complex is isomorphic to the “forested graph complex” which has significantly simpler orientation data. In the presence of hairs, this isomorphism does not quite go through, but one can still simplify the description of a hairy Lie graph slightly. In the hairy Lie graph of Figure 3, this can be done by removing the grey ovals and noticing that they could be recovered as a neighborhood of the subgraph spanned by all vertices and unoriented edges. Thus a hairy Lie graph may be represented by a uni-trivalent graph whose univalent vertices are labeled by vectors in $v$ and some
of whose internal edges are oriented, with the property that the subgraph $G_u$ spanned by the unoriented edges is a forest containing all of the vertices of $G$. Orientation data consists of ordering the components of the forest, and specifying a cyclic ordering of the half edges incident to each trivalent vertex. The central edge in an IHX relation must be an unoriented edge.

The 1-chains $C_1\mathcal{H}$ are generated by hairy graphs $G$ such that the subgraph $G_u$ spanned by unoriented edges is a (maximal) tree.

The first homology of $\mathcal{H}$ is the quotient of $C_1\mathcal{H}$ by the image of the boundary operator $\partial_2: C_2\mathcal{H} \to C_1\mathcal{H}$. As in the associative case, we begin with some observations about the image of $\partial_2$.

Lemma 7.1. Let $G$ be a Lie graph in $C_1\mathcal{H}$. If some unoriented edge separates $G$ into two non-trivial components, then $G$ is in the image of $\partial_2$.

Proof. Suppose an edge $e \in G_u$ separates $G$ into two non-trivial components, i.e. components which are not a single vertex. In the Lie graph $H$ obtained by orienting $e$, the unoriented subgraph $H_u$ has two components, and all oriented edges other than $e$ have both ends in one or the other of these components. Thus all terms of $\partial_2(H)$ are zero except for $H_e = \pm G$. \qed

In particular, if there is an unoriented tree attached to the rest of $G$ at a single vertex, then $G$ is in the image of $\partial_2$ (see Figure 4).

Thus a generator of $C_1\mathcal{H}$ may be thought of as a connected graph $G$ with orientations on the edges in the complement of some maximal tree $T \subset G$, and with single edges (called hairs) attached to the edges of $G$.

Lemma 7.2. If $G$ is a Lie graph in $C_1\mathcal{H}$, then hairs attached to the same unoriented edge of $G$ may be permuted modulo $\operatorname{im} \partial_2$. 

Figure 3. A hairy Lie graph with rank 2 and degree $4 + 1 + 2 = 7$
**Proof.** This is a consequence of the IHX relation and Lemma 7.1:

![Figure 4. Attached unoriented tree](image)

Lemma 7.3. If \( G \) is a Lie graph in \( C_1 \mathcal{H} \), then the hairy Lie graph obtained by moving a hair to the other end of an oriented edge is equal to \( G \) modulo \( \text{im} \partial_2 \).

**Proof.** Notice that

\[
\partial_2 \left( \begin{array}{c} v_1 \\ v_2 \\ v_3 
\end{array} \right) = \begin{array}{c} v_1 \\ v_2 \\ v_3 
\end{array}
\]

Recall that the rank of a hairy graph is its first Betti number. Since the boundary operator \( \partial_\mathcal{H} \) preserves rank, the chains \( C_k \mathcal{H} \) decompose into subcomplexes

\[ C_k \mathcal{H} = \bigoplus_r C_{k,r} \mathcal{H}, \]

where \( C_{k,r} \mathcal{H} \) is spanned by connected hairy graphs of rank \( r \). On the level of homology this gives

\[ H_k(\mathcal{H}) = \bigoplus_{r \geq 0} H_{k,r}(\mathcal{H}), \]

where \( H_{k,r}(\mathcal{H}) = H_k(C_{k,r} \mathcal{H}) \). The next three propositions give elementary calculations of \( H_{1,r} \) for \( r \leq 2 \). In the following sections we identify \( H_{1,r} \) for all \( r \geq 2 \) with a certain twisted cohomology of \( \text{Out}(F_r) \) and then calculate this twisted homology for \( r = 2 \) in terms of modular forms.

**Proposition 7.4.** For \( O = \text{Lie} \) the rank zero part of \( H_1(\mathcal{H}) \) is \( H_{1,0}(\mathcal{H}) \cong \wedge^3 V \).

**Proof.** A rank 0 Lie graph has no oriented edges, so is a union of trees; since we are only looking at \( C_1 \mathcal{H} \) there is only one tree. If this tree has more than 3 leaves then it is in the image of \( \partial_2 \). A tripod, on the other hand, cannot be in the image of \( \partial_2 \), so \( H_{1,0}(\mathcal{H}) \) is
spanned by tripods. If we choose an ordering for the labels of each tripod, the map sending the labels to their wedge product is an isomorphism $H_{1,0} \to \bigwedge^3 V$.

**Proposition 7.5.** For $O = \text{Lie}$ the rank one part of $H_1(\mathcal{H})$ is $H_{1,1}(\mathcal{H}) \cong \bigoplus_{k \geq 0} S^{2k+1}V$

**Proof.** Let $L_{1,1}$ denote the subspace of $C_{1,1}\mathcal{H}$ generated by Lie graphs $G$ consisting of a single oriented loop with hairs attached. The number of hairs must be odd, since otherwise $G$ has an orientation reversing automorphism (see Figure 5), giving $G = -G \hookrightarrow i.e. G = 0$ in $\mathcal{H}$. The complementary subspace $G_{1,1}$ is in the image of $\partial_\mathcal{H}$ by Lemma 7.1. We claim that the map sending $G$ to the product of the labels on its hairs induces an isomorphism $H_{1,1}(\mathcal{H}) \cong \bigoplus_{k \geq 0} S^{2k+1}V$.

Using Lemma 7.2 we see that the map is a well-defined isomorphism on $L_{1,1}$, so it suffices to check that the image of $C_{1,2}\mathcal{H}$ under $\partial_\mathcal{H}$ is contained in $G_{1,1}$.

Let $H$ be a generator of $C_{1,2}\mathcal{H}$. Then $H$ is represented by two trivalent planar trees joined by one oriented edge which connects them, plus another oriented edge. If the second oriented edge has both ends in one tree, then $\partial_\mathcal{H}(H)$ has a separating unoriented edge, so is in $G_{1,1}$. If the second oriented edge also joins the two trees, then both terms of the boundary push all the hairs together, and by Lemma 7.2, they are actually the same graph modulo boundaries. The signs are opposite, so $\partial_\mathcal{H}(H) = 0$ for this type of graph.

**Proposition 7.6.** For $O = \text{Lie}$, $H_{1,2}(\mathcal{H})$ is isomorphic to the subspace of the polynomial ring $k[V \oplus V]$ characterized by the conditions:

1. $f(x, y) = f(y, x)$
2. $f(x, y) = -f(-x, y)$
3. $f(x, y) + f(y, -x - y) + f(-x - y, x) = 0$

**Proof.** The chain group $C_{1,2}(\mathcal{H})$ is generated by rank 2 trivalent graphs $G$ with hairs attached. A maximal tree (in this case a single edge) is specified, and the other edges are oriented. To calculate $H_{1,2}(\mathcal{H})$ we need to account for the relations in $C_{1,2}(\mathcal{H})$ arising from IHX and antisymmetry and calculate the image of $\partial_\mathcal{H}(C_{2,2}(\mathcal{H}))$.

There are only two trivalent graphs in rank 2: the theta graph and the eyeglass graph, so $C_{1,2}$ decomposes as $\text{Tri} \oplus \text{Gla}$, where $\text{Tri}$ is generated by theta graphs and $\text{Gla}$ is generated by eyeglass graphs. Any hairy graph based on the eyeglass graph is a boundary by Lemma 7.1, i.e. $\text{Gla} \subset \text{Im}(\partial_\mathcal{H})$.

Figure 5. Orientation-reversing automorphism
Using IHX, we can push the hairs off of the tree edge of $G \in \text{Tri}$, decomposing $G$ as a sum of theta graphs with hairs only on the oriented edges. If there is an even number of hairs on one of these edges, the IHX relation using the tree edge, together with antisymmetry relations, shows that $G$ is zero modulo boundaries: one term of the IHX relation is based on an eyeglass graph, and the other is equal to the first, giving $2G = 0$ (see Figure 6).

Using anti-symmetry relations, we can make $G$ planar, put the tree edge in the center and flip each hair to the right-hand side of its oriented edge. We then associate to each edge the monomial formed by multiplying the labels on the hairs. We consider each of these as a monomial in a separate copy of $V$, one with variables $x$ and one with variables $y$, and form their product $f(x, y)$. By Lemma 7.2 the order the hairs are attached is irrelevant modulo boundaries, and the monomial $f(x, y)$ completely determines $G$. The fact that number of hairs on each oriented edge is odd means the degree of $f(x, y)$ is odd in $x$ and in $y$, which can be rewritten as condition (2).

The symmetry of the theta graph together with the anti-symmetry relation in $\text{Lie}$ imposes condition (1).

Finally, condition (3) identifies the rest of the image of $\partial_H$. Let $G'$ be a generator of $C_{2,2}$ based on the theta graph. Then $G'$ consists of two tripods connected by three oriented edges, and $\partial_H(G')$ is a sum of three terms. Pushing the hairs off of the tree edge in each term corresponds exactly to forming the summands of the third condition.

**Example.** Let $x_1, \ldots, x_n, y_1, \ldots, y_n$ be coordinate functions for $V \oplus V$, where $x_i$ represent the first factor and and $y_i$ the second. Suppose $k \geq 2$. Then define a polynomial function

$$f_{2k}(x_1, \ldots, x_n, y_1, \ldots, y_n) = x_1 y_2^{2k-1} - x_2 y_1 y_2^{2k-2} + y_1 x_2^{2k-1} - y_2 x_1 x_2^{2k-2}.$$ 

One may verify that $f_{2k}$ satisfies the three conditions above, so it represents a nontrivial homology class for $H_{1,2}$ with $2k$ hairs. In particular, this picks up the first degree in which $H_{1,2} \neq 0$, when the number of hairs is 4. Later, when we see the connection to modular forms, we will see that $f_{2k}$ is connected to the Eisenstein series.
7.3. $H_{1,r}(\mathcal{H})$ and twisted cohomology of $\text{Out}(F_r)$. In this section and the next we will give deeper insight into the results of the calculation of $H_{1,2}$, as well as giving a general formula for $H_{1,r}$. This general formula is in terms of the cohomology of $\text{Out}(F_r)$ with coefficients in the polynomial ring $k[V^\oplus r] = k[V \otimes k^r]$, where the action is via the quotient $\text{Out}(F_r) \to \text{GL}_r$ and the standard action of $\text{GL}_r$ on $k^r$. We begin by explaining how this is computed, in order to relate it to hairy graph homology. For a detailed explanation, with trivial coefficients, of the relation between (unhairy) Lie graph homology and the cohomology of $\text{Out}(F_r)$ we refer to [4], section 3.

The group $\text{Out}(F_n)$ acts on a contractible cube complex $K_n$, called the spine of Outer space (see [6]). Stabilizers of this action are finite, so by a standard argument (see, e.g. Brown’s book [1]), the quotient $K_n/\text{Out}(F_n)$ has the same cohomology as $\text{Out}(F_n)$ with trivial rational coefficients. The argument adapts easily to the case of non-trivial coefficients in a rational representation as follows:

**Proposition 7.7.** Let $X$ be a contractible CW complex on which a group $G$ acts with finite point stabilizers, let $C^*(X)$ be the cellular cochain complex for $X$, and suppose that $M$ is a $G$-module which is a vector space over a field of characteristic 0. Then $C^*(X) \otimes_G M$ is a cochain complex computing $H^*(G; M)$.

**Proof.** We follow the discussion from [1]. Namely, on p.174, equation 7.10, there is a first-quadrant spectral sequence

$$E_1^{pq} = \bigoplus_{\sigma \in \Sigma_p} H_q(G_\sigma, M_\sigma) \Rightarrow H_s(G, M)$$

where $\Sigma_p$ is a set of representatives of $G$-orbits of $p$-cells, $G_\sigma$ is the stabilizer of $\sigma$ and $M_\sigma$ is $M$ twisted by the “orientation character.” Dually, there is a first-quadrant spectral sequence

$$E_1^{pq} = \bigoplus_{\sigma \in \Sigma_p} H^q(G_\sigma, M_\sigma)$$

converging to $H^*(G, M)$. But $G_\sigma$ is finite, and $M_\sigma$ is a $\mathbb{Q}G_\sigma$-module, so $H^q(G_\sigma, M_\sigma) = 0$ for $q > 0$ (see, e.g. Corollary 10.2, p. 84 of [1]). Thus $E_1^{pq} = 0$ for all $q > 0$, i.e. the spectral sequence collapses to simply a cochain complex in the row $q = 0$.

Now observe that $E_1^{r,0} = \bigoplus_{\sigma \in \Sigma_r} H^0(G_\sigma, M_\sigma) = \bigoplus_{\sigma \in \Sigma_r} (M_\sigma)_G \sigma = C^0(X) \otimes G M$. \qed

For any vector space $W$, denote by $k[W]$ the ring of polynomial functions on $W$. Note that $k[W]$ is graded by polynomial degree, i.e. $k[W] = \bigoplus_k k[W]_k$, where $k[W]_k$ denotes homogeneous polynomials of degree $k$.

**Theorem 7.8.** For $O = \text{Lie}$ and $r \geq 2$ there is a graded isomorphism

$$H_{1,r}(\mathcal{H}) \cong H^{2r-3}(\text{Out}(F_r); k[V^\oplus r]),$$

where $H_{1,r}(\mathcal{H})$ is graded by the number of hairs, and the grading on $H^{2r-3}(\text{Out}(F_r); k[V^\oplus r])$ is given by polynomial degree:

$$H^{2r-3}(\text{Out}(F_r); k[V^\oplus r]) \cong \bigoplus_{k \geq 0} H^{2r-3}(\text{Out}(F_r); k[V^\oplus r])$$
Proof. By Proposition 7.7 applied to the spine $K_r$ of Outer space, $H^{2r-3}(\text{Out}(F_r); M)$ can be computed using the cochain complex $C^* = C^*K_r \otimes_{\text{Out}(F_r)} M$. Recall from [4] that each $k$-dimensional cube of $K_r$ is determined by a graph $G$ equipped with a $k$-edge subforest $\Phi$ and a marking, which is a homotopy equivalence $g$ from $G$ to a fixed rose $R_n$ whose petals are identified with the generators of $F_n$. The cube $(G, \Phi, g)$ is oriented by ordering the edges of the forest $\Phi$. The coboundary operator is a sum of two operators $\delta_E$ and $\delta_C$, which add an edge to the forest in all possible ways and expand a vertex into a forest edge in all possible ways, respectively.

The top-dimensional cubes of $K_r$ correspond to marked trivalent graphs with maximal trees, so are $(2r - 3)$-dimensional. The $(2r - 4)$-dimensional cubes correspond either to trivalent graphs or to graphs with one 4-valent vertex. Using $\delta_C$ to expand the 4-valent vertex in the three possible ways gives the terms of the IHX relation, so the quotient

$$\tilde{C}^{2n-3}K_r = C^{2n-3}K_r / \text{im}(\delta_C)$$

is generated by trivalent marked graphs modulo IHX relations using edges of their maximal trees, and

$$H^{2r-3}(\text{Out}(F_r); k[V^{2g}]) = \tilde{C}^{2n-3}K_r \otimes_{\text{Out}(F_r)} k[V^{2g}] / \text{im}(\delta_E \otimes 1).$$

We now turn to the hairy graph homology computation

$$H_{1,r}(\mathcal{H}) = C_{1,r}\mathcal{H} / \text{im}(\partial_H).$$

A generator $G$ of $C_1\mathcal{H}$ can be represented (modulo anti-symmetry and IHX relations) by a planar trivalent tree with some pairs of leaves joined by oriented edges and the rest labeled by elements of $V$. If $G$ has a separating unoriented edge which is not a hair then $G$ is a boundary by Lemma 7.1. If all separating edges are hairs, then removing these hairs results in a trivalent core graph $G$. If any hairs are on unoriented edges of $G$, then they may be moved using IHX relations to the oriented edges. Using anti-symmetry relations, we may flip each hair to the right-hand side of its oriented edge. Thus as generators for $H_{r,1}(\mathcal{H})$ we may take trivalent graphs $G$ of rank $r$ such that the unoriented edges form a maximal tree $T$ and the oriented edges $\tilde{e}$ have labeled hairs attached to the right-hand side. Modulo $\text{im}(\partial_H)$, the order of the hairs on each oriented edge does not matter.

We can now define the isomorphism

$$f : C_{1,r}\mathcal{H} / \text{im}(\partial_H) \to \tilde{C}^*K_r \otimes_{\text{Out}(F_r)} k[V^{2g}] / \text{im}(\delta_E \otimes 1).$$

Let $G$ be a generator of $C_{1,r}\mathcal{H}$, as described above. To get a marking $g : G \to R_n$, we collapse the unoriented edges of $G$ to obtain a rose $G/T$, then choose a homeomorphism from $G/T$ to the standard rose $R_n$ preserving the orientations on the edges. If $g(\tilde{e}) = x_i$ set $m_i \in k[V]$ equal to the product of the labels of the hairs on $\tilde{e}$. Then

$$f(G) = (G, T, g) \otimes m_1 \ldots m_r \in k[V^r].$$

This map is well-defined and surjective; in particular it does not depend on the choice of the homeomorphism from $G/T$ to $R_n$ since the symmetric group permuting the petals of $R_n$ is a subgroup of $\text{Out}(F_r)$. To see that it is injective, note that $\partial_H$ coincides with $\delta_E$ under this map. \qed
Remark 7.9. This proof does not work to compute $H_i(\mathcal{H})$ for $i > 1$ since we allowed ourselves to slide hairs across oriented edges using Lemma 7.3. Unfortunately, there is no analogue of Lemma 7.3 for hairy graphs in $C_i\mathcal{H}$ with $i > 1$.

7.4. $H_{1,2}(\mathcal{H})$ and modular forms. In this section, we let $k = \mathbb{C}$. For $r = 2$ we have identified

$$H_{1,2}(\mathcal{H}) \cong H^1(\text{Out}(F_2), \mathbb{C}[V \oplus V]).$$

Since the abelianization map $F_2 \to \mathbb{Z}^2$ induces an isomorphism $\text{Out}(F_2) \cong \text{GL}_2(\mathbb{Z})$ we can use the representation theory of $\text{GL}_2(\mathbb{Z})$ to calculate this group precisely. The answer involves the dimension $s_k$ of the space of weight $k$ cuspidal modular forms for $\text{SL}_2(\mathbb{Z})$.

For $k \neq 2$ even, it is given by

$$s_k = \begin{cases} \lfloor k/12 \rfloor - 1 & \text{if } k \equiv 2 \pmod{12} \\ \lfloor k/12 \rfloor & \text{if } k \not\equiv 2 \pmod{12} \end{cases}.$$

Recall also that the Weyl module $S_{(k,\ell)}V$ is the irreducible representation of $\text{GL}(V)$ corresponding to the partition $(k,\ell)$.

**Theorem 7.10.** There is a graded isomorphism

$$H_{1,2}(\mathcal{H}) \cong \bigoplus_{k,\ell \geq 0} (S_{(k,\ell)}V)^{\oplus \lambda_{k,\ell}}$$

where $\lambda_{k,\ell} = \begin{cases} s_{k-\ell+2} & \text{if } \ell \text{ is even} \\ s_{k-\ell+2} + 1 & \text{if } \ell \text{ is odd.} \end{cases}$

The grading on $H_{1,2}(\mathcal{H})$ is by the number of hairs (=degree - 2) and on $\bigoplus_{k,\ell \geq 0} (S_{(k,\ell)}V)^{\oplus \lambda_{k,\ell}}$ is by $k + \ell$.

**Proof.** By Theorem 7.8, $H_1(\mathcal{H}) \cong H^1(\text{Out}(F_2); \mathbb{C}[V \oplus V])$. Since the natural map from $\text{Out}(F_2)$ to $\text{GL}_2(\mathbb{Z})$ is an isomorphism, we may instead compute $H^1(\text{GL}_2(\mathbb{Z}); \mathbb{C}[V \oplus V])$.

Set $P_V = \mathbb{C}[V \oplus V] = \mathbb{C}[V \otimes \mathbb{C}^2]$. Then $P_V$ is a $\text{GL}(V) \otimes \text{GL}_2(\mathbb{C})$-module, which by Schur-Weyl duality can be decomposed as

$$P_V = \bigoplus_{\lambda} S_\lambda V \otimes S_\lambda \mathbb{C}^2.$$

(See [11] p.218 and p.257.) The Weyl module $S_\lambda \mathbb{C}^2$ is zero unless $\lambda = (k,l)$ is a Young diagram with only two rows, and

$$S_{(k,\ell)} \mathbb{C}^2 = C_{(\det)^{\ell}} \otimes H_{k-l}$$

where $H_{k-l}$ is the space of homogeneous polynomials of degree $k-l$, see [7].
Thus

\[
H^1(GL_2(\mathbb{Z}); P_V) = H^1\left(GL_2(\mathbb{Z}); \bigoplus_{k \geq l \geq 0} S_{(k,l)} V \otimes H_{k-l}\right) \\
\cong \bigoplus_{k \geq l \geq 0} H^1(GL_2(\mathbb{Z}); H_{k-l}) \otimes S_{(k,l)} V
\]

where the action of GL(2, \mathbb{Z}) on H_{k-l} is standard if l is odd and twisted by the determinant map if l is even.

The cohomology 5-term exact sequence of the extension

\[
1 \rightarrow SL_2(\mathbb{Z}) \rightarrow GL_2(\mathbb{Z}) \rightarrow \mathbb{Z}/2\mathbb{Z} \rightarrow 1
\]

reads

\[
0 \rightarrow H^1(\mathbb{Z}/2\mathbb{Z}, H_m) \rightarrow H^1(GL_2(\mathbb{Z}), H_m) \rightarrow H^1(SL_2(\mathbb{Z}), H_m)_{\mathbb{Z}/2\mathbb{Z}} \rightarrow H^2(\mathbb{Z}/2\mathbb{Z}, H_m) \rightarrow H^2(GL_2(\mathbb{Z}), H_m)
\]

Since \( H^1(\mathbb{Z}/2\mathbb{Z}; M) = H^2(\mathbb{Z}/2\mathbb{Z}; M) = 0 \) for any vector space M over a field of characteristic 0 this gives

\[ H^1(GL_2(\mathbb{Z}); H_m) \cong H^1(SL_2(\mathbb{Z}); H_m)_{\mathbb{Z}/2\mathbb{Z}}. \]

The computation is now completed using Eichler-Shimura theory (see, e.g. [13], p. 246-247). The action of \( \mathbb{Z}/2\mathbb{Z} \) is induced by conjugation by \( \epsilon = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix} \), and

\[ H^1(SL_2(\mathbb{Z}); H_m) \cong H^1_+ \oplus H^1_- \]

where \( H^1_+ \) is the \((+1)\)-eigenspace of the action, and \( H^1_- \) is the \((-1)\)-eigenspace. These eigenspaces are given by

\[ H^1_+ \cong M_{m+2}^0 \]

where \( M_{m+2}^0 \) is the vector space of weight \( m+2 \) cuspidal modular forms for the full modular group SL_2(\mathbb{Z}) and

\[ H^1_- \cong M_{m+2}^0 \oplus E_{m+2} \]

where \( E_{m+2} = 0 \) if m is odd or if \( m = 0 \), and otherwise \( E_{m+2} \) is the one dimensional space spanned by the Eisenstein series in degree \( m+2 \). Therefore, if the action of GL_2(\mathbb{Z}) is standard, we get

\[ H^1(GL_2(\mathbb{Z}); H_m) \cong H^1(SL_2(\mathbb{Z}); H_m)_{\mathbb{Z}/2\mathbb{Z}} \cong H^1_+ \cong M_{m+2}^0 \]

and if the action is twisted by the determinant we get

\[ H^1(GL_2(\mathbb{Z}); H_m) \cong H^1(SL_2(\mathbb{Z}); H_m)_{\mathbb{Z}/2\mathbb{Z}} \cong H^1_- \cong M_{m+2}^0 \oplus E_{m+2}. \]

Since \( M \otimes S_{(k,l)} V \cong (S_{(k,l)} V)^{\dim M} \), plugging this result into expression (1) above gives the theorem. \( \square \)
We remark that that $M^0_{m+2}$ is zero when $m$ is odd. Here is a table of all Weyl modules which appear in $H_{1,2}(H)$ for graphs with at most 14 hairs, i.e. $k + l \leq 14$. The notation $(k, \ell)^m$ means that $S_{(k, \ell)}V$ appears $m$ times.

8. Cycles in the unstable homology of $\text{Mod}(g, s)$, $\text{Out}(F_n)$ and $\text{Aut}(F_n)$

For each cyclic operad $\mathcal{O}$ and symplectic vector space $V$, the abelianization map $h_V \rightarrow h_V^{ab}$ is a Lie algebra morphism, where the bracket on $h_V^{ab}$ is trivial. If $\mathcal{O}$ is finite dimensional at each level continuous cohomology is defined (see Definition 1.5) so abelianization induces a backwards map $H^*_c(h_V^{ab}) \rightarrow H^*_c(h_V)$. Taking $\text{Sp}$-invariants gives a map

$$PH^*_c(h_V^{ab})^{\text{Sp}} \rightarrow PH^*_c(h_V)^{\text{Sp}}.$$  

where $P$ denotes the submodule of primitive elements in the Hopf algebra $H^*_c(h_V)^{\text{Sp}}$. Using the fact that the cohomology of a finite-dimensional abelian Lie algebra is simply the exterior algebra on its dual space, the domain of this map is often easy to compute and gives rise to potentially non-trivial elements in the image.

For $\mathcal{O} = \text{Assoc}$ and $\mathcal{O} = \text{Lie}$ a theorem of Kontsevich identifies $PH^*_c(h_V)^{\text{Sp}}$ (for suitable $V$) with the homology of mapping class groups of punctured surfaces and outer automorphism groups of free groups, and a theorem of Gray relates similar cohomology groups to the homology of $\text{Aut}(F_n)$. In this section we show how to exploit these theorems together with the map (2) above to construct cycles for the homology of these groups.

8.1. Mapping class groups of punctured surfaces. Let $\text{Mod}(g, s)$ denote the mapping class group of a surface of genus $g$ with $s$ punctures, i.e. the group of isotopy classes of homeomorphisms which preserve the set of punctures (not necessarily pointwise). Set $V_n = k^{2n}$ with the standard symplectic form and $V_\infty = \lim_{n \rightarrow \infty} k^{2n}$; write $h_n$ for $h_{V_n}$ and $h_\infty = h_{V_\infty}$. Kontsevich’s theorem for $\mathcal{O} = \text{Assoc}$ reads:

**Theorem 8.1.** [4, 17, 16] For $\mathcal{O} = \text{Assoc},$

$$PH^*_c(h_\infty)^{\text{Sp}} \cong \bigoplus_{s > 0} H_{4g + 2s - k - 4}(\text{Mod}(g, s); k).$$

To use the map (2) to find classes in $H_*(\text{Mod}(g, s))$ we must now compute $PH^*_c(h_\infty^{ab})^{\text{Sp}}$. By Theorem 6.5 we have that $h_V^{ab} \cong W_1 \oplus W_2$ where $W_1 = [V \otimes^3]_{Z_3}$ and $W_2 = (\wedge^2 V)/\mathbb{Z}$. In [21] Morita calculated

$$P(\wedge^k W_2)^{\text{Sp}} = (\wedge^k W_2)^{\text{Sp}} \cong \begin{cases} k & \text{if } k \equiv 1 \mod 4 \text{ and } k \geq 5 \\ 0 & \text{otherwise} \end{cases}$$
Since the result of the calculation is independent of $V$ we can take duals on the finite level and conclude that $\text{PH}^{4r+1}(\mathfrak{h}_\infty^a)^{\text{Sp}}$ contains a copy of $k$ for each $r \geq 1$. Applying the map (2) now gives a cocycle in $\text{PH}^{4r+1}(\mathfrak{h}_\infty)^{\text{Sp}}$ for each $r \geq 1$, which corresponds via Kontsevich’s theorem to a cycle in $H_{4r+1}(\text{Mod}(1,4r+1))$. In [2] it was shown that all of these cycles in fact represent non-trivial homology classes.

We have only used the degree 2 piece $W_2$ of the abelianization to construct these homology classes. Using $W_1$ as well we can construct many more cycles; for example it is easy to compute that $\left(\bigwedge^2 W_1 \otimes \left(\bigwedge^2 W_2\right)^{\text{Sp}}\right) \neq 0$, giving 2-dimensional cycles for $\text{Mod}(1,3)$ and $\text{Mod}(2,1)$. However, we do not know whether these cycles are non-trivial in homology. In the sequel to this paper we will show how to produce cycles on moduli space (of any genus) by using classes in $H_k(\mathcal{H})$ for $k > 1$, potentially yielding even more unstable homology classes.

8.2. The outer automorphism group $\text{Out}(F_n)$. Again we set $V_n = \mathbb{R}^{2n}$ with the standard symplectic form, $V_\infty = \lim_{n \to \infty} \mathbb{R}^{2n}$, and write $\mathfrak{h}_n$ for $\mathfrak{h}_{V_n}$ and $\mathfrak{h}_\infty = \mathfrak{h}_{V_\infty}$. Kontsevich’s theorem for $\mathcal{O} = \text{Lie}$ reads:

**Theorem 8.2.** [4, 17, 16] For $\mathcal{O} = \text{Lie}$, $\text{PH}_c^k(\mathfrak{h}_\infty)^{\text{Sp}}$ is non-zero only in even degrees $2d$, in which case

$$\text{PH}_c^k(\mathfrak{h}_\infty)^{\text{Sp}}(2d) \cong H_{2d-k}(\text{Out}(F_{d+1}); k).$$

Following the abelianization map with the trace map yields Lie algebra morphisms

$$\mathfrak{h}_n \to \mathfrak{h}_n^a \hookrightarrow H_1(\mathcal{H}_n)$$

where both $\mathfrak{h}_n^a$ and $H_1(\mathcal{H}_n)$ are thought of as abelian Lie algebras, graded by degree. In degree $d$, these maps induce backwards maps

$$\sum_{d_1 + \ldots + d_k = d} H_1(\mathcal{H}_n(d_1))^* \wedge \ldots \wedge H_1(\mathcal{H}_n(d_k))^* \to H^*(\mathfrak{h}_n)(d),$$

using the fact that $H^*(\mathfrak{a}) = \bigwedge \mathfrak{a}^*$ for finite-dimensional abelian Lie algebras $\mathfrak{a}$. Taking the primitive part of the Sp-invariants and letting $n$ go to infinity yields a map

$$\mu : \lim_{n \to \infty} P\left(\sum_{d_1 + \ldots + d_k = d} H_1(\mathcal{H}_n(d_1))^* \wedge \ldots \wedge H_1(\mathcal{H}_n(d_k))^*)^{\text{Sp}} \to \text{PH}_c^*(\mathfrak{h}_\infty)^{\text{Sp}}(d).$$

Thus by combining elements of the first homology of the hairy graph complex, we obtain cocycles in $\text{PH}_c^*(\mathfrak{h}_\infty)^{\text{Sp}}(d)$, which by Kontsevich’s theorem can be identified with cycles in $H_{2d-k}(\text{Out}(F_{d+1}); k)$. We illustrate this with two concrete examples below.

8.2.1. Morita’s original cycles. Morita’s original series of cycles was constructed from elements of $\mathfrak{h}_1^a$ in degree $d = 2k - 1$. When pushed by the trace into hairy graph homology, these correspond to $H_{(1,1)}(\mathcal{H}_V)(2k-1) \cong S^{2k-1}V$. In hairy graph homology generators of $H_{(1,1)}(\mathcal{H}_V)(2k-1)$ are represented by oriented loops with $2k - 1$ hairs attached, labeled by elements of $V$.

A straightforward computation shows that $W_{2k-1} := [(S^{2k-1}V)^* \wedge (S^{2k-1}V)^*)^{\text{Sp}} \cong k$. The generator of $W_{2k-1}$ corresponds to two hairy loops, with the hairs on one paired
with the hairs on the other; the labels have disappeared and the generator is independent of $V$. Since this graph is connected, it represents a primitive class. Since in a Hopf algebra the dual to the submodule of primitives is primitive with respect to the dual Hopf algebra structure, we get $W^*_{2k-1} \subset P [(S^{2k-1}V)^* \wedge (S^{2k-1}V)^*]^{Sp}$. The image of the generator of $W^*_{2k-1}$ under the map $\mu$ above is in $PH^2_c(\mathfrak{h}_\infty)^{Sp}$ and under Kontsevich’s theorem corresponds to the $k$-th Morita class, in $H_{4k-4}(\text{Out}(F_{2k}); k)$.

8.2.2. New classes from cusp forms. Recall that $H_1(\mathcal{H}_V) \supset H_{1,2}(\mathcal{H}_V) \supset (S_{(k,l)}V)^{\lambda_{k,l}}$. We will use the piece with $(k, l) = (2m, 0)$ to construct new cohomology classes in $PH^2_c(\mathfrak{h}_\infty)^{Sp}$. In this case the exponent $\lambda_{(m,0)}$ is equal to $s_{2m+2}$, the dimension of the space $M^0_{2m+2}$ of cusp forms of weight $2m + 2$, and in fact we have

$$(S_{(2m,0)}V)^{2m+2} = M^0_{2m+2} \otimes S_{(2m,0)}V = M^0_{2m+2} \otimes S^{2m}V.$$ 

**Lemma 8.3.** $[(M^0_{2m+2} \otimes S^{2m}V) \wedge (M^0_{2m+2} \otimes S^{2m}V)]^{Sp}$ is isomorphic to $S^2(M^0_{2m+2})$.

**Proof.** Let $U = M^0_{2m+2} \otimes S^{2m}V = k^s \otimes S^{2m}V$. In order to compute $[\Lambda^2 U]^{Sp}$, we first compute $[U \otimes U]^{Sp}$, and then divide by the alternating $\mathbb{Z}_2$-action. But notice that $[U \otimes U]^{Sp} \cong (k^s \otimes k^s) \otimes [S^{2m}V \otimes S^{2m}V]^{Sp} \cong (k^s \otimes k^s) \otimes k$.

since $[S^{2m}V \otimes S^{2m}V]^{Sp} \cong k$. Now to calculate $[\Lambda^2 U]^{Sp}$, we take the $\mathbb{Z}_2$ invariants. $\mathbb{Z}_2$ acts on $k^s \otimes k^s$ by permuting the factors with a sign, and it acts on $k$ by multiplication by $-1$. Thus we get $[(k^s \otimes k^s) \otimes k]^{\mathbb{Z}_2} = S^2(k^s) = S^2(M^0_{2m+2})$.  

Generators of $S^2(M^0_{2m+2})$ are represented in hairy graph homology by two rank two hairy graphs with $2m$ hairs each; the hairs are connected in pairs by oriented edges, resulting in a connected graph of rank $2m + 3$ (and degree $4m + 4$). So we get

$S^2(M^0_{2m+2})^* \subset P [H_1 \mathcal{H}_n(2n+2)^* \wedge H_1 \mathcal{H}_n(2n+2)^*]^{Sp}$.

Since this is independent of $n$, applying the map $\mu$ together with Kontsevich’s theorem yields the following result.

**Theorem 8.4.** There is an injection $S^2(M^0_{2k})^* \hookrightarrow Z_{4k-2}(\text{Out}(F_{2k+1}); k)$ into cycles for $\text{Out}(F_{2k+1})$.

The first nonzero $M^0_{2k}$ occurs when $k = 6$, yielding a cycle in $Z_{22}(\text{Out}(F_{13}))$. This is beyond the range in which we can compute whether this is a nonzero homology class.

8.3. The automorphism group $\text{Aut}(F_n)$. Kontsevich’s theorems for mapping class groups and outer automorphism groups of free groups have been adapted by Gray [12] to yield information about the homology of automorphism groups of free groups. The basic modification needed in hairy graph homology is to add a distinguished hair which marks a basepoint for the graph. To keep track of the vertex which contains the distinguished hair,
we think of the operad element tinting the vertex as a coefficient (with a distinguished vertex). This complicates the algebra somewhat, as we now explain.

Let $L_V$ denote the submodule of the free Lie algebra on $V$ spanned by elements of degree at least 2. Then $h_V$ acts on $L_V$ by derivations, and we can form the homology groups $H_*(h_V; L_V)$. The homology $H_*(h_V; L_V)$ is not a Hopf algebra, but it is a Hopf module over $H_*(h_V)$, where in general $M$ is said to be a Hopf module over the Hopf algebra $H$ if there are maps $H \otimes M \to M$ (this is the module structure) and $M \to H \otimes M$ (this is the comodule structure) satisfying various compatibility axioms. The module structure for $H_*(h_V; L_V)$ is analogous to the structure for homology with trivial coefficients; we refer to [12] for details.

Primitives in a Hopf module are defined to be solutions of the equation $\Delta (x) = 1 \otimes x$. Just as in the case of Hopf algebras, the dual of a Hopf module is also a Hopf module, and primitives get sent to primitives when taking duals. As in the case of trivial coefficients, primitivity translates to connectedness of graphs on the graph homology level.

**Theorem 8.5.** [12] For $\mathcal{O} = \text{Lie}$,
\[
PH_k^c(h_{\infty}; L_{\infty})^{Sp} \cong \bigoplus_{r \geq 2} H^{2r-1-k}(\text{Aut}(F_r); \mathbb{Q}),
\]
where $h_{\infty}$ acts on $L_{\infty}$ by derivations.

We want to use the dual form of this isomorphism, so we pause to introduce some notation. Let $M_n = \bigoplus M_n(d)$ be a graded vector space where each graded summand is finite dimensional. Suppose $\cdots \to M_{n+2} \to M_{n+1} \to M_n \to \cdots$ is a sequence of graded linear maps. Define
\[
M_\uparrow := \lim_{n \to \infty} \bigoplus_{d} M_n(d)^*.
\]
The dual statement of Theorem 8.5 is then
\[
PH_c^k(h_{\infty}; L_{\infty}^\uparrow)^{Sp} \cong \bigoplus_{r \geq 2} H^{2r-1-k}(\text{Aut}(F_r); \mathbb{Q}).
\]

The action of $h_{\infty}$ on $L_{\infty}$ induces an action of $h_{\infty}^{ab}$ on $L_{\infty} = L_{\infty}/(h_{\infty} \cdot L_{\infty})$. Abelianization $h_{\infty} \to h_{\infty}^{ab}$ then induces a backwards map on continuous cohomology
\[
H_c^*(h_{\infty}^{ab}; L_{\infty}^\uparrow) \to H_c^*(h_{\infty}; L_{\infty}^\uparrow),
\]
where we emphasize that $L_{\infty}^\uparrow := \lim_{n \to \infty} \bigoplus_d L_{V_n}^*(d)$ and similarly $L_{\infty}^\uparrow := \lim_{n \to \infty} \bigoplus_d L_{V_n}^*(d)$. Taking $Sp$-invariants and then primitives gives
\[
PH_c^*(h_{\infty}^{ab}; L_{\infty}^\uparrow)^{Sp} \to PH_c^*(h_{\infty}; L_{\infty}^\uparrow)^{Sp}
\]

We now want to relate the domain of this map to hairy graph homology. To this end, let $V'$ be the vector space generated by $V$ and an additional hyperbolic pair of vectors $b$ and $b^*$, and let $[h_{V'}]^{ab}$ be the subspace of $h_{V'}$ spanned by spiders where the label $b$ appears...
there are basepoint

This is because with exactly one hair labeled classes represented by all such polynomials. The subspace satisfies the three conditions of Theorem 7.6, so also represents a non-zero element of \( \text{Aut}(V') \). Now \( h_V \cdot L_V \) is in the kernel of this map, since acting by an element of \( h_V \) on \( L_V \) corresponds to taking a commutator in \( h_V \).

We also have a map \( [h_V^\beta]^b \rightarrow H_1(\mathcal{H}_{V'})^b \) induced by the trace. Combining these gives the following chain of maps:

\[
\left( \bigwedge (h_v^\beta)^\dagger \otimes [H_1(\mathcal{H}_{V'})^\dagger] \right) \rightarrow \left( \bigwedge (h_v^\beta)^\dagger \otimes ([h_v^\beta]^{\dagger}) \right) \rightarrow \left( \bigwedge (h_v^\beta)^\dagger \otimes S^1 \right) \rightarrow H^*(h_v; L_\infty),
\]

inducing

\[
P \left( \bigwedge (h_v^\beta)^\dagger \otimes (H_1(\mathcal{H}_{V'})^\dagger) \right) \rightarrow PH^*(h_v; L_\infty)^{\text{Sp}}
\]

As in the last section, we can identify pieces of \( P \left( \bigwedge (h_v^\beta)^\dagger \otimes (H_1(\mathcal{H}_{V'})^\dagger) \right) \) to give us classes in \( PH^*(h_v; L_\infty)^{\text{Sp}} \) which correspond via Gray’s theorem to cycles for the homology of \( \text{Aut}(F_n) \). We illustrate this in the following theorem.

**Theorem 8.7.** There is a series of cycles \( e_{4k+3} \in Z_{4k+3}(\text{Aut}(F_{2k+3}); \mathbb{k}) \) for \( k \geq 1 \).

**Proof.** We first identify some convenient submodules of \( H_1(\mathcal{H}_{V'}) \). In particular we look at the part of \( \mathcal{H}_{1,2} \) with \( 2k \) hairs.

In Example 7.2 we identified a nonzero element \( f_{2k} \) of \( H_{1,2}(\mathcal{H}) \subset H_1(\mathcal{H}) \) in terms of polynomials in \( \mathbb{k}[V' \oplus V'] \), namely

\[
f_{2k} = x_1y_2^{2k-1} - x_2y_1^{2k-1} + y_1x_2^{2k-1} - y_2x_1^{2k-1},
\]

where the \( x_i \) are the coordinates of the first copy of \( V' \) and the \( y_i \) are the coordinates of the second copy.

The polynomial \( f_{2k} \) does not generate an \( \text{Sp} \)-invariant subspace of \( H_1(\mathcal{H}) \), so we generalize it as follows. Let \( v \) be a nonzero linear combination of the \( x_i \) and let \( w, w_1, \ldots, w_{2k-2} \) be nonzero linear combinations of the \( y_i \). Let \( u \mapsto \bar{u} \) denote the involution on \( V' \oplus V' \) which swaps the factors, i.e. swaps \( x_i \) with \( y_i \). Then the polynomial

\[
vw_1 \cdots w_{2k-2} - \bar{v}w_1 \cdots w_{2k-2} + \bar{v}ww_1 \cdots \bar{w}_{2k-2} - vw_1 \cdots \bar{w}_{2k-2}
\]

satisfies the three conditions of Theorem 7.6, so also represents a non-zero element of \( H_{1,2}(\mathcal{H}) \), represented by a theta graph with \( 2k - 1 \) hairs attached. Let \( M \) be the span of the classes represented by all such polynomials. The subspace \( M^b \) is spanned by theta graphs with exactly one hair labeled \( b \) and no hairs labeled \( b^* \). We claim that \( M^b \cong V \otimes S^{2k-2}V \). This is because \( M^b \) is generated by polynomials where \( v \) is the coordinate function for the basepoint \( b \); these are uniquely determined by the second summand of the polynomial, and there are \( V \otimes S^{2k-2}V \) such summands.
Figure 7. Hairy Lie graph representation of $e_7$

Let $S^{2k-1}V$ be the summand of $h^\text{ab}_V$ whose generators are represented by oriented loops with $2k-1$ hairs attached. Then $[S^{2k-1}V \otimes M]^\Sigma_p \cong [S^{2k-1}V \otimes (V \otimes S^{2k-2}V)]^\Sigma_{2p} \cong k$ and we get a 1-dimensional subspace of $h^\text{ab}_V \otimes (h^\text{ab}_V)^\bot$. This is represented by pairing the hairs of the loop with $2k-1$ hairs to the hairs of a theta graph with one basepoint hair and $2k-1$ other hairs (see Figure 7 for $k = 2$). This graph is connected so represents a primitive class, which we denote $e_{4k-1}$, for $k \geq 2$.

In general, the cycles $e_{4k-1}$ correspond in $H_1(\mathcal{H})$ to the partitions $\lambda = (2k+1,1)$, which appear with multiplicity $s_{2k+2} + 1$, where the “+1” corresponds to the Eisenstein series. Since there are no cusp forms up to $k = 4$, these cycles correspond to Eisenstein series up to $k = 4$. We suspect that they also correspond to Eisenstein series for larger $k$.

Computer calculations show that the first two cycles $e_7$ and $e_{11}$ are nontrivial in homology. This brings the total list of known nontrivial homology groups for Aut and Out to: $H_4(\text{Out}(F_4); \mathbb{Q})$, $H_8(\text{Out}(F_6); \mathbb{Q})$, $H_{12}(\text{Out}(F_8); \mathbb{Q})$, $H_4(\text{Aut}(F_4); \mathbb{Q})$, $H_7(\text{Aut}(F_5); \mathbb{Q})$ and $H_{11}(\text{Aut}(F_7); \mathbb{Q})$. The first three classes are part of Morita’s original series. The fact that $H_{12}(\text{Out}(F_8); \mathbb{Q}) \neq 0$ was recently proven by Gray [12]. The fact that $H_7(\text{Aut}(F_5); \mathbb{Q}) \neq 0$ was proven by Gerlits [10], though the interpretation in terms of the Eisenstein series is new.

Remark 8.8. In all of these cases, except $H_{12}(\text{Out}(F_8))$ and $H_{11}(\text{Aut}(F_7))$ which are unknown, computer calculations due to Gerlits and Ohashi [10, 23] show that the homology spaces are one dimensional, so that these classes generate everything.

9. HAIRY LIE GRAPHS AND AUTOMORPHISMS OF PUNCTURED 3-MANIFOLDS

Let $M_{n,s}$ be the compact 3-manifold obtained from the connected sum of $n$ copies of $S^1 \times S^2$ by deleting the interiors of $s$ disjoint balls. In [15] the group $\Gamma_{n,s}$ is defined to be the quotient of the mapping class group of $M_{n,s}$ by the normal subgroup generated by Dehn twists along embedded 2-spheres. By a theorem of Laudenbach $\Gamma_{n,0} \cong \text{Out}(F_n)$ and $\Gamma_{n,1} \cong \text{Aut}(F_n)$.

Hairy graph homology is related to the groups $\Gamma_{n,s}$ as follows. Let $\mathcal{H}^{n,s}_V$ be the part of the hairy Lie graph complex generated by connected graphs of rank $n$ with $s$ hairs.

Theorem 9.1. There are isomorphisms

$$H_k(\mathcal{H}^{n,s}_V) \cong H^{2n+s-2-k}(\Gamma_{n,s}; V^\otimes_s) \otimes_{\Sigma_s} V^\otimes_s.$$
where the symmetric group $\Sigma_n$ acts simultaneously on $C^*(\Gamma_{n,s})$ and $V^\otimes s$.

When $s = 0$, we recover the isomorphism $H_k(\mathcal{H}^{n,0}) \cong H^{2n-2-k}(\text{Out}(F_n); k)$ described in [4], since the 0-hair part of the hairy graph complex is just the Lie graph complex. When $s = 1$, we get $H_k(\mathcal{H}^{n,1}) \cong H^{2n-1-k}(\text{Aut}(F_n); k) \otimes V$.

**Proof of Theorem 9.1.** This is a straightforward adaptation of the proof for $s = 0$, using Proposition 7.7 and the spaces $A_{n,s}$ defined in [15] in place of Outer space. What we are calling hairs correspond to “thorns” in [15]. The only wrinkle is that hairs are labeled by elements of $V$ and do not come with a distinguished ordering, as in the definition of $A_{n,s}$. Hence to get an equality, we need to take the coinvariants under the action of the symmetric group which permutes the ordering on the thorns. This gives an isomorphism of $H_*(\mathcal{H}^{n,s})$ with $H_*(([C^*(\Gamma_{n,s}) \otimes V^\otimes s]_{\Sigma_n})$ with some degree shift. Over the rationals, taking coinvariants commutes with homology. So we get an isomorphism $H_*(\mathcal{H}^{n,s}; k) \otimes_{\Sigma_n} V^\otimes s$. On the other hand $C^*(\Gamma_{n,s}) \otimes V^\otimes s \cong \text{Hom}(C_*(\Gamma_{n,s}), V^\otimes s)$, so we get $H_*(\mathcal{H}^{n,s}) \otimes_{\Sigma_n} V^\otimes s = H_*(\text{Hom}(C_*(\Gamma_{n,s}), V^\otimes s))_{\Sigma_n}$.
